Even more interesting, and in some respects more important, is the southern group of Siah-Posh Kafirs, who occupy the upland valleys between Kohistán and the Swati district, and even visit the northern pastures west of the Dora Pass, crossing the Hindu-Kush at an altitude of some 16,000 feet. In these mountain fastnesses they have hitherto succeeded in preserving intact not only their primitive speech, usages, and religion, but even their political independence. Although included within the limits of the Amir's possessions, no Afghan ventures to penetrate into their territory, which till quite recently was almost a *terra incognita*. By Major Tanner, and the few other Europeans by whom they have been visited, they are described as of a pure Caucasic type, with regular features, blue and dark eyes, hair varying from brown to black, and altogether the most European in appearance of all Asiatic peoples. With the British rulers of India they claim kindred, trace their descent from Alexander the Great, differ from other Asiatics in the use of chairs and tables, and speak a pure Aryan dialect, showing marked affinities to Sanskrit. Some few in the extreme south and west have become assimilated in speech and religion to their Afghan neighbours, and these Safi and Nemchi, as they are called, serve as the medium of communication between the two races. For obvious reasons the masters of India should cultivate the friendship and alliance of the Siah-Posh highlanders, who, from the name of their most powerful *gali*, or tribe, sometimes take the collective name of Kamoji.

The south-western slopes of the Hindu-Kush north of Kábul are held by several little known tribes vaguely known as KOHISTÁNI, or "Hill men." They occupy the whole district between Kafiristán and the Koh-i-Baba. They are mainly Tajiks, that is, Iranians, probably descended of Persian settlers in pre-Mohammedan times, and still speak a rude Persian dialect. Although now Mohammedans of the Sunni sect, they appear to be an unruly people, owing a reluctant allegiance to the Amir, in this and some other respects differing from the other Tajiks found dispersed in settled communities elsewhere in Afghanistan and throughout the whole of Central Asia. The name, referred to the root *táj* = *crown*, is supposed to mean "crowned," indicating the imperial race that once held sway from the Bosporus to the Indus. But the sceptre has long passed from Irán to Turán even in Persia itself, where the reigning dynasty belongs to the Qajár tribe, of Turkoman stock.

As already stated, both slopes of the North Afghan highlands are in almost exclusive possession of Mongolic peoples from the Koh-i-Baba to Herat, east and west, and from Afghan Turkestan southwards to the Ghor uplands. Here both branches of the Mongolo-Tatar group are represented, the Mongols proper by the HAZARAHS and the AIMAKS, the Tatars by the TURKOMANS and the KATAGHÁNI USBEGS. With the Hazarahs are sometimes grouped the JEMSHÍDIS and FIRUZ-KHOH of the province of Herat. But both of these numerous communities appear to be fundamentally of Iranian stock although the type has to some extent been modified by contact with the surrounding Mongolo-Tatar tribes.

Thus it appears that, as above remarked, the Afghan proper nowhere occupy any territory along their northern frontier, but, except at Herat, have everywhere been driven into the interior of the plateau by the intruding Central Asiatic races. It is further to be noted that although they hold the Usbegs of the Tirband-i-Turkestan escarpment and of the Turkestán lowlands in military subjection, they have hitherto failed to reduce either the Aimaks of the Ghor district or the Hazarahs of the Koh-i-Baba and Safed-Koh ranges. The direct route from Herat to Kábul through this region has not only never yet been traversed by any European explorer, but is absolutely inaccessible to the Afghans themselves. Hence it is that the military and trade route between these two points is deflected a long way southwards to the Helmand basin and to Kandahar, whence it laboriously creeps through the Ghazni highlands to the Kábul valley.[1] Hence also the vast strategic importance of such places as Kandahar and Girishk on the Helmand, which depend not, as is generally supposed, so much on the lie of the land, as on the ethnical conditions of its inhabitants. The future masters of the Aimak and Hazarah tribes will not only secure the rich prize of the Ghor region with its untouched mines of gold, silver, copper, lead, iron, coal, sulphur, rubies, and emeralds, but will also command the direct and natural route from Herat to the Indus, *vid* Kábul and Peshawar.

Meantime, these Aimaks and Hazarahs, neglected by statesmen, continue to interest our men of science alone. Their flat features, tawny complexion, scant beard, oblique eyes, and prominent zygomatic arches, betray their common Mongolic descent, while the somewhat corrupt Persian dialect generally spoken by both implies long contact in their new homes with Iranian culture. They are also Mohammedans; the Aimaks of the Sunni sect, the Hazarahs of the Shiah sect, in this respect differing from all other Mongolian tribes, who are exclusively Buddhist. Another proof of Persian influence is the settled life of the Hazarahs,[2] who have long ceased to be nomads, and now occupy permanent villages of small thatched houses. In late years they have begun to migrate towards Herat, where they find employment on the public works.

The Aimaks, or Char Aimaks, that is "Four Hordes," so named from their four main divisions, occupy, besides the Ghor country, extensive tracts on the northern slopes of the border ranges, on the hills encircling Herat, and beyond the frontier in Khorasán. Some communities of the Herat district have preserved their mother-tongue, and their chief tribe even still bears the Mongol name of Kipchak. They also retain the old *urdu*, or tents of felt or skins, and usually grouped round a central tower or stronghold occupied by the chief. They are described as altogether more savage and ferocious than their Hazarah neighbours, and are even said to drink the blood of the slain in battle (Elphinstone).

With the fall of Merv all the hitherto independent Turkoman tribes passed under the sceptre of the "White Czar," except the SARIKS and the SALORS. Soon after that event the Sariks of the Merv oasis gave in their submission to the number of about 10,000 families. Meanwhile that district was invaded in 1860 by the Tekke Turkomans. The Salors, its original masters, withdrew higher up the Murghab valley, where they are still found within about the Afghan frontier, on the route between Me

[1] The direct route is little over 360 miles, the detour by Kandahar 550.

[2] Probably so named from the Persian *hazár* = a thousand, in allusion to their numerous tribal subdivisions.

Herat. They do not recognise the authority of the Amir of Kábul, and should the Czar, who is about to assume the title of "Emperor of Central Asia," claim the allegiance of this outlying Central Asiatic tribe, here will be a fruitful source of future complications. Their submission would at once advance the Russian frontier far into Afghan territory and up the Murghâb valley to within easy distance of Herat from the north. The route in this direction is well known, and constantly traversed by traders from Khiva, Bokhara, and Samarkand. It appears to present no greater difficulties than the more westerly route crossing the Barkhut ridge recently surveyed by Lessar.

There remain to be mentioned the KATAGHÁNI USBEGS, who form the bulk of the population in Afghan Turkestán. They belong to the same ethnical group as the Usbegs of the Khanates, and have even some settlements in Bokhara beyond the Oxus. They are mostly agriculturists and traders, Sunnite Mohammedans of pure Turki speech, and bear with reluctance the hard yoke of their Afghan masters. Their sympathies are entirely with their northern kinsmen, and as the country Kunduz, Balkh, Maimene) belongs geographically to the Aralo-Caspian basin, it is difficult to see how further rectifications of frontier can ultimately be prevented in this direction. Exponents of advanced public opinion in Russia already openly claim the whole of this region to the crest of the Hindu-Kush as properly belonging to the ruler of Central Asia, and their arguments are largely based on ethnological grounds.

Table of the North Afghan Border Tribes

Tribe	Locality	Population[1]
CAUCASIC STOCK		
Siah-Posh	Kafiristán	150,000
Badakhshi	Badakhshán	160,000
Wakhi	Wakhán	3,000
Shugnáni	Shugnán	25,000
Kohistáni	Kohistán	?
Furuz-Khoi	Prov. Herat, Murghâb Valley	30,000 tents
Jemshidi	Prov. Herat, Khushk Valley	12,000 families
Tajiks	Herat, Balkh, &c.	200,000 ?
Afghans	Herat	100,000 ?
MONGOLIC STOCK		
Hazarahs	Hazárajat ... ... Koh-i-Baba, Safed-Koh ...	300,000
Aimaks	Ghor, Herat, Khorasán ...	350,000
Salor Turkomans	About Martshag, Murghâb Valley	30,000
Kataghâni Usbegs	Afghan Turkestán, Bokhara	600,000

A. H. KEANE

ANTHROPOMETRIC PER-CENTILES

I SEND the following Table, partly to exemplify what I trust will be found a convenient development of a statistical method that I have long advocated, and partly for its intrinsic value, whatever that may be. It will at events interest those of the 9337 persons measured in the Anthropometric Laboratory at the late International Health Exhibition, who may wish to discover their rank among the rest.

Its meaning is plain, and will be understood by the help of a single example, for which I will take the line referring to Strength of Squeeze among males. We see that a discussion was made of 519 measurements in that respect, of men whose ages ranged between 23 and 26; that 75 per cent. of them were able to exert a squeeze with their strongest hand (the squeeze was measured by a spring dynamometer) that surpassed 67 lbs. of pressure; that 90 per cent. could exert one that surpassed 71; 80 per cent. one that surpassed 76; and so on. The value which 50 per cent. exceeded, and 50 per cent. fell short of, is the Median Value, or the 50th per-centile, and this is practically the same as the Mean Value; its amount is 85 lbs. This line of the Table consequently presents an exact and very complete account of the distribution of strength in one respect among the middle 90 per cent. of any group of males of the tabular ages similar to those who were measured at the laboratory. The 5 per cent. lowest and the 5 per cent. highest cannot be derived directly from it, but their values may be approximately inferred from the run of the tabular figures, supplemented by such deductions as the Law of Error may encourage us to draw. Those who wish to apply this law will note that the probable error is half the difference between the 25th and the 75th per-centile, which can easily be found by interpolation, and they will draw the per-centiles that correspond respectively to the median value *minus* twice, three times, and three-and-a-half times the probable error, at the graduations 8·7, 2·4, 0·8, and those that correspond to the median value *plus* those amounts, at the graduations 91·3, 97·6, and 99·2. The Table is a mere statement of observed fact; there is no theory whatever involved in its construction, beyond simple interpolations between values that differ little from one another and which have been found to run in very regular series.

It may be used in many ways. Suppose, for example, that a man of the tabular age, viz. above 23 and under 26, and who could exert a squeeze of 80 lbs., desired to know his rank among the rest, the Table tells him at once that his strength in this respect certainly exceeds that of 30 per cent. of those who were measured, because if it had been only 79 lbs. it would have done so. It also tells him that his strength does not exceed that of 40 per cent. of the rest, since it would have required a pressure of 82 lbs. to have done this. He therefore ranks between the 30th and the 40th per-centile, and a very simple mental sum in proportion shows his place to be about the 33rd or 34th in a class of 100.

The Table exhibits in a very striking way the differences between the two sexes. The 5th male per-centile of strength of squeeze is equal to the 90th female per-centile, which is nearly but not quite the same as saying that the man who ranks 5th from the bottom of a class of 100 males would rank 10th from the top in a class of 100 females. The small difference between the two forms of expression will be explained further on. If the male per-centiles of strength of squeeze are plotted on ruled paper, beginning with the lowest, and if the female per-centiles are plotted on the same paper, beginning with the highest, the curves joining their respective tops will be found to intersect at the 7th per-centile, which is the value that 7 of the females and 93 of the males just surpass. Therefore, if we wished to select the 100 strongest individuals out of two groups, one consisting of 100 males chosen at random, and the other of 100 females, we should take the 100 males and draft out the 7 weakest of them, and draft in the 7 strongest females. Very powerful women exist, but happily perhaps for the repose of the other sex, such gifted women are rare. Out of 1657 adult females of various ages measured at the laboratory, the strongest could only exert a squeeze of 86 lbs. or about that of a medium man. The population of England hardly contains enough material to form even a few regiments of efficient Amazons.

The various measurements of males surpass those of females in very different degrees, but in nearly every particular. A convenient way of comparing them in each case is that which I have just adopted, of finding the per-centile which has the same value when reckoned from the lower end of the male series, and from the higher end of the female series. When this has been done, the position o

[1] Population mostly conjectural.

ANTHROPOMETRIC PER-CENTILES

Values surpassed, and Values unreached, by various percentages of the persons measured at the Anthropometric Laboratory in late International Health Exhibition

(*The value that is unreached by n per cent. of any large group of measurements, and surpassed by* 100–*n* of them, *is called its* per-centile)

Subject of measurement	Age	Unit of measurement	Sex	No. of persons in the group	Values surpassed by per-cents. as below: 95	90	80	70	60	50	40	30	20	10
					Values unreached by per-cents. as below: 5	10	20	30	40	50	60	70	80	90
Height, standing, without shoes	23–51	Inches	M.	811	63·2	64·5	65·8	66·5	67·3	67·9	68·5	69·2	70·0	71·3

			F.	276	36	39	43	47	49	52	55	58	62	67
Swiftness of blow.	23–26	Feet per second	M.	516	13·2	14·1	15·2	16·2	17·3	18·1	19·1	20·0	20·9	22·3
			F.	271	9·2	10·1	11·3	12·1	12·8	13·4	14·0	14·5	15·1	16·3
Sight, keenness of —by distance of reading diamond test-type	23–26	Inches	M.	398	13	17	20	22	23	25	26	28	30	32
			F.	433	10	12	16	19	22	24	26	27	29	31

per-centiles arranged in order of their magnitude are as follows:—Pull, 4; Squeeze, 7; Breathing capacity, 10; Height, 14; Weight, 26; Swiftness of blow, 26; Keenness of sight, 37. We conclude from them that the female differs from the male more conspicuously in strength than in any other particular, and therefore that the commonly used epithet of "the weaker sex," is peculiarly appropriate.

The Table was constructed as follows:—I had groups of appropriate cases extracted for me from the duplicate records by Mr. J. Henry Young, of the General Register Office. I did not care to exhaust the records, but requested him to take as many as seemed in each case to be sufficient to give a trustworthy result for these and other purposes to which I desired to apply them. The precise number was determined by accidental matters of detail that in no way implied a selection of the measurements. The summarised form in which I finally took them in hand, is shown in the two upper lines of the following specimen:—

Height, Sitting, of Female Adults, Aged 23–50, *in inches*

29-	30-	31-	32-	33-	34-	35-	36-	37-	
2	8	52	116	226	227	108	31	5	Total 775
2	10	62	178	404	631	739	770	775	Abscissæ 0 to 775
30	31	32	33	34	35	36	37	38	Corresponding Ordinates

The meaning of the two upper lines is that in a tot 775 observations there were 2 cases measuring 29 under 30 inches, 8 cases measuring 30 and unde inches, and so on. The third line contains the sum the entries in the second line reckoned from the begin and is to be read as follows:—2 cases under 30 inche cases (= 2 + 8) under 31 inches, 62 cases (= 2 + 8 + under 32 inches, and so on.

I plotted these 775 cases on French "sectional" p which is procurable in long and inexpensive rolls, crossways by lines 1 millimetre apart. I counted th line as 0° and the 776th as 775°. Supposing the mea ments to have been plotted in the order of their m tude, in succession between these lines, the first v stand between 0° and 1°, the second between 1° an and so on. Now we see from the Table that the se measurement was just short of 30 inches, consequ the third measurement was presumably just beyon therefore the abscissa whose value is 2°, and w separates the second from the third measurement, fairly be taken to represent the abscissa of the ord that is equal to 30 inches exactly. Similarly, the abs whose value is 10° divides the measurement that is under 31 inches from that which is presumably just a it, and may be taken as the abscissa to that ord whose precise value is 31°, and so on for the rest. fourth line of the Table gives the ordinates thus d mined for the abscisse whose values are entered them in the third line. I dotted the values of ordinates in their right places on the sectional p and joined the dots with a line, which in every except the breathing capacity, fell into a strik regular curve. (I cannot account for this one p exception, save on the supposition of the somewhat

gular mixture of town and country folk, and of sedentary and active professions among the persons measured, but I have not yet verified this surmise.) Per-centiles were then drawn to the curve corresponding to abscissæ that were respectively 5 per cent., 10 per cent., 20 per cent., &c., of the length of the base line. As the length of the base-line was 275, these per-centiles stood at the graduations 13°·8, 27°·5, 55°·0, &c. Their values, as read off on the sectional paper, are those which I have given in the Table.

It will be understood after a little reflection that the 9th rank in a row of 10, the 90th rank in a row of 100, and the 900th rank in a row of 1000, are not identical, and that none of them are identical with the 90th per-centile. There must always be the difference of one half-place between the post which each person occupies in a row of *n* individuals, numbered from 1 to *n*, and that of the corresponding graduations of the base on which they stand, and which bear the same nominal value, because the graduations are numbered from 0 to *n* and begin at a point one half-place short of the first man, and end at one half-place beyond the last man. Consequently the graduations corresponding to the posts of the 9th, 90th, and 900th man in the above example, refer to the distance of those posts from the beginning at 0 of their several base lines, and those distances are related to the lengths of the base lines in the proportions of 8·5 : 10, 89·5 : 100, and 899·5 : 1000, which when reckoned in per-cents of the several base lines are 85, 89·5, and 89·95 respectively. The larger the number of places in the series, the more insignificant does this half-place become. Moreover, the intrusion of each fresh observation into the series separates its neighbours by almost double that amount, and propagates a disturbance that reaches to either end, though it is diminished to almost nothing by the time it has arrived there. We may therefore ignore the existence of this theoretically troublesome half-place in our ordinary statistical work.

There is a latent source of error that might affect such statistics as these, as well as many others that are drawn in the usual way, which has not, so far as I know, been recognised, and deserves attention. It is due to uncertainty as to the precise meaning of such headings as 30, 31, &c. If the measurements, no matter whether they were made carefully or carelessly, are read off from the instruments with great nicety, then a reading such as 30·4 would fall in the column 30–, and the mean of all the entries in such a column might fairly be referred to a mean value of 30·5.

But if the instruments are roughly read, say, to the nearest half inch, the reading of a real instrumental value of 30·99, and even that of a real value of 30·76, would both be entered in the column 31–. The column 30– would then contain measurements whose real instrumental values ranged between 29·75 and 30·75, and the column 31– would contain those that ranged between 30·75 and 31·75: consequently, the means of all the entries in those columns respectively should be referred, not to 30·5 and 31·5, but to 30·25 and to 31·25. An error of a quarter of an inch in the final results might easily be occasioned by the neglect to note the degree of minuteness with which the instruments were read, and I strongly suspect that many statistical tables are affected by this generally unrecognised cause of error. The measurements at my laboratory were read to the nearest tenth of an inch and to the fraction of a pound, so I can afford to disregard this consideration. There was, however, a slight bias in the habit of entering round numbers, which should have been, but were not (because I neglected to give the necessary instructions), rateably divided between the columns on either side.

A fuller description of the results of the measurements at the laboratory will appear next February or March in the forthcoming number of the *Journal* of the Anthropological Institute, at which place the original data will ultimately be deposited.

FRANCIS GALTON

NOTES

IT having become known to some of the friends of the late Mr. Henry Watts, the well-known chemist, whose death occurred very suddenly on the 30th of last June, that his widow and family are in very straitened circumstances, an informal meeting was recently held at the Royal Institution. Those present resolved to form themselves into a committee, with power to add to their number, in order to collect a fund for the benefit of Mrs. Watts and those of her children who are not of an age to provide for their own support. Dr. Atkinson consented to act as secretary, and Dr. Perkin, President of the Chemical Society, as treasurer. Among the names on the committee are those of Sir F. A. Abel, Prof. H. E. Armstrong, Mr. William Crookes, Dr. Warren De La Rue, Prof. James Dewar, Prof. G. C. Foster, Dr. J. H. Gladstone, Prof. A. G. V. Harcourt, Dr. Hugo Müller, Dr. William Odling, Dr. W. H. Perkin, Dr. B. W. Richardson, Prof. W. Chandler Roberts, Sir H. E. Roscoe, Dr. W. J. Russell and Prof. A. W. Williamson. Mr. Watts's public labours for the advancement of chemical science may be said to have begun with the translation of Gmelin's "Handbook of Chemistry," the admirable English edition of which was prepared and edited for the Cavendish Society by him. This work occupies eighteen large octavo volumes, of which the first appeared in 1849, and the last in 1871. A work scarcely, if at all, inferior to this in magnitude, and one which has perhaps been of even greater service to English chemists, both scientific and industrial, is Watts's great "Dictionary of Chemistry," which appeared from 1863 to 1881, in eight volumes, containing altogether nearly 9700 pages. Mr. Watts also edited and largely added to the second volume of the late Prof. Graham's "Elements of Chemistry," published in 1858; he prepared several editions of Fownes's well-known "Manual of Chemistry," which he almost entirely re-wrote and made into virtually a new work; and in conjunction with Mr. Ronalds and Dr. Richardson, he prepared for Messrs. Baillière an elaborate treatise on chemical technology. Up to the time of his death, and for about thirty years previously, Mr. Watts was editor of the *Journal* of the Chemical Society, and in this capacity, as well as in that of librarian to the Chemical Society, he became personally known to and gained the friendship of very many among the Fellows of the Society. But although Mr. Watts's life was one of unremitting labour, the money return for his work was barely sufficient to enable him to provide for the daily wants of a delicate wife and a numerous family. It was not possible for him to provide for their future needs. But if he could not leave behind him pecuniary resources, he accumulated esteem and affection among all who knew him, which, it is confidently hoped, will prove a valuable legacy for those who were dependent on him. The facts of the case show that there is great need of whatever practical proof of their regard for him and appreciation of his labours Mr. Watts's friends, and English chemists generally, may be willing to make. For many years Mrs. Watts has been in ill-health, so that she cannot do anything for her own support and that of her family. One son is a permanent invalid, and the four youngest children have still to be educated. A considerable expenditure is therefore unavoidable for a good many years to come, if the children are to have a fair chance of a start in life. A considerable sum has already been promised in the way of subscriptions, but much more will have to be done in order that any substantial benefit may accrue to Mrs. Watts and her young family. Subscriptions will be received and acknowledg

by the Secretary, Dr. Edmund Atkinson, Portesbery Hill, Camberley, Surrey, or by the Treasurer, Dr. W. H. Perkin, the Chestnuts, Sudbury, Harrow.

M. MILNE EDWARDS has been nominated by the French Government Grand Officer of the Legion d'Honneur.

LECTURES in connection with the London Society for the Extension of University Teaching have been going on in Whitechapel now for more than six years. The number of tickets sold for the lectures during this period has been close upon 2000, and the ticket-holders have been nearly all artisans. The reports of the examiners, appointed by the Universities' Board, have shown that many of those attending the lectures are real students—a conclusion which is also borne out by the fact that the same subjects have been studied for several years in succession. It has been felt that a good reference library and reading room would be a great help to the existing students, as well as a means of attracting others. An opportunity for providing these advantages is now afforded in the "Universities' Settlement" in Toynbee Hall, where the lectures will in future be given, and a reading room be opened to the students. The Committee desire to stock this room with a good reference library—especially in the subjects of history, political economy, physics, and physiology—and will be very grateful for any assistance in this attempt to further higher education among working men and women in East London. Any one willing to help, either with books or with money, is requested to communicate either with E. T. Cook, 22, Albemarle Street, W. (Sec. London Society for the Extension of University Teaching), or Bolton King, 28, Commercial Street, E. (Hon. Sec. Whitechapel Local Committee).

THE mean-time clocks at the Royal Observatory, Greenwich, were put forward twelve hours a little before midnight of December 31, in order that the commencement of the civil day and the astronomical day might be identical from January 1, 1885. The public clock near the entrance to the Observatory will thus indicate the hours as recommended by the Washington Conference—*i.e.* reckoning from 0h. to 24h., starting from midnight. As the Greenwich observations for 1885 will not be printed until 1886, the proposed method can be tried for a year before the necessity of deciding on its adoption will arise. In writing to the Rev. T. E. Espin, President of the Liverpool Astronomical Society, the Astronomer-Royal says:—"The change that we propose to make at Greenwich is for the present provisional only, as it appears essential that it should be generally accepted by astronomers before it is introduced into any published observations. I am very anxious to avoid the confusion which would result from two systems of reckoning time being in use among astronomers. But as regards the ordinary public, it seems to me clear that for civil reckoning the day must commence at midnight, and in order to assist in familiarising the public with the reckoning from 0h. to 24h., I propose on January 1 to alter our public clock (which is numbered from 0h. to 24h.) by 12h., so that it will show civil reckoning instead of the old astronomical reckoning."

CHEMISTS will regret to learn that Dr. Edward Divers, Principal of the Imperial College of Engineering, Tokio, Japan, has met with a very serious accident, which it is feared will result in the loss of one of his eyes. He is understood to have been engaged in work in connection with the theory of acids, when a bottle, supposed to contain terchloride of phosphorus, exploded, causing him very severe injuries. Dr. Divers is well known as the author of many valuable chemical papers read before the Royal and other scientific societies.

MR. ALFRED TYLOR, F.G.S., who died on December 31 last, will be remembered as a promoter of technical education at a time when its vital importance was little recognised, and the English manufacturing mind was generally set against it. He was intimately associated with Dr. von Steinbeis, whose energy in this direction did so much to give the little kingdom of Wurtemburg its industrial prominence in Germany. Mr. Tylor's work, "Education and Manufactures," arising out of his Jury Report on Metal Work at the Exhibition of 1862, was translated into German under the title "Industrie und Schule" (Stattgart, 1865), and also appeared in Swedish. Mr. Tylor sat for some years on the Council of the Geological Society. His geological papers relate principally to the flow of rivers as connected with the erosion of valleys and the deposit of gravel-beds; they contain much systematised information, for instance, as to the mechanical action of the Mississippi and the Ganges. It is well known that his study of river-valleys and drift-gravels led him to the hypothesis of a post-glacial time of enormous rainfall, which he called the "pluvial period." The term, though not generally accepted, is found of use, to judge from its not unfrequent appearance in geological works.

THE death is announced, at the age of seventy-four years, of Dr. Andrew Findlater, for so many years connected with the editorial department of Messrs. W. and R. Chambers. Dr. Findlater wrote several of the scientific volumes in Chambers' well-known "Educational Course," and edited a revised edition of the "Information for the People." But his most important undertaking was the editing of "Chambers's Encyclopædia," the scientific articles in which hold so high a place, mainly through Dr. Findlater's knowledge, discernment, and tact in obtaining the right men to act as contributors. Dr. Findlater was offered the editorship of the new edition of the "Encyclopædia Britannica," but was induced to decline it.

WE read in the German papers that the Greek Government has offered to supply the marble, as it did in the case of Lord Byron's monument in England, for a national monument to be erected to Wilhelm Müller, the father of Prof. Max Müller, in his native town of Dessau. Wilhelm Müller is best known as the poet of the "Müller-lieder," beautifully set to music by Schubert. But the Greek Government, in the name of the Greek nation, wished to express its recognition of the great services rendered to the cause of Greek independence by Wilhelm Müller, "the Philhellenic Tyrtæus," whose "Griechenlieder" belong to the classical literature of Germany. Committees have been formed in Germany, Italy, Greece, and America. The English committee consists of Mrs. Jenny Lind-Goldschmidt, Sir Theodore Martin, Sir Robert Morier, Sir George Grove, J. A. Froude, and Prof. Buchheim. Subscriptions are received by Messrs. Williams and Norgate, 14, Henrietta Street, W.C.

BAVARIAN papers report the death, after a short illness, of Dr. Philip von Jolly, Professor of Mathematical and Experimental Physics in the University of Munich, in the seventy-fifth year of his age.

A NEW association has been established among the students of the University of Paris. The first step of this institution has been the organisation of a public manifestation in honour of M. Chevreul, the director of the Museum, who is just completing his 100th year. He is the first French academician who has reached this advanced age since the death of Fontenelle, who died about 1750, a few days before completing his century. A little before his death Fontenelle was heard to say to one of his friends asking if he complained of some illness, "I have no suffering, but I am feeling merely an increased difficulty of living."

WE learn from *Science* that the "cold-wave flag," which has been inaugurated by the U.S. Signal Service during the autumn, is intended to be displayed not only at the ve

stations of the Signal Service, but also at as many railway-stations and post-offices as possible, in order to spread the widest notice of the coming change of weather. The service cannot at present undertake to provide the flags or to pay for special telegrams to numerous local display-stations; but the cost of the flags (white, six feet square, with a two-foot black square in centre) is moderate, and can easily be borne by those interested in securing early indications of falling temperature; and in several parts of the country the telegrams are sent to all the stations on certain railroads that co-operate with the Signal Service, and thus promptly distribute weather forecasts to the towns along their routes. It is probable that the coming year will see a considerable extension of this kind of weather service.

M. JAMIN, the Perpetual Secretary of the Paris Academy of Sciences, has published, in the January issue of *Revue des Deux Mondes*, the essay on balloons, which we announced a few weeks ago. The academician takes a very moderate view of the success of the Meudon and Point du Jour experiments.

THE terrestrial disturbance in Southern Spain, which began with violent earthquake shocks on Christmas night, still continues, and other earthquakes are reported from Austria and Italy. From Vienna information comes of repeated shocks on the 4th inst. in the hot-spring district of Southern Styria, during which some slight damage was done, while on the afternoon of the same day a shock, perhaps of the same earthquake, was felt at Susa, near Mont Cenis, and one of greater force on the morning of the following day (January 5) at Velletri, near Rome. The seismic instruments at the observatory in Rome and at Rocca di Papa showed unusual activity on the 5th and previous days, especially at midday, and at night the mineral springs in the Island of Ischia have risen in temperature. It would thus appear that the present is a period of unusual seismic disturbance throughout Southern Europe. In Spain no day has passed since the 25th ult. without one or more severe shocks in the disturbed area. On the 31st ult. the tenth violent shock in a week occurred in Granada—the people left their houses for the night—and up to that date 10,000 people had left the town altogether. On the same day and on the 1st inst. shocks continued at Jaen, Torrox, Malaga, Benamargoza, and Velez Malaga. At Torrox buildings were thrown down, and the town has been wholly abandoned. At Nerja the church was damaged, and at Arenas del Rey 500 persons were either killed or injured. On the 1st inst. and the morning of the 2nd fresh shocks were felt at Nerja, Algarrobo, Granada, and Malaga. A number of towns and villages are reported completely destroyed and deserted. On the 3rd shocks were felt along the Mediterranean coast of Granada and Malaga. Up to noon on the 3rd inst., according to official returns, 673 bodies were recovered from the ruins of towns in the province of Granada alone. On that day the shocks were renewed in Loja, Alhama, Jaen, and Velez Malaga, fissures being made in the ground. The town of Alhama, which has suffered most severely of all, is composed of two parts, the upper and lower. During the earthquake on Christmas night the upper town, situated on the side of a valley, fell into the lower portion. Over 1500 houses were destroyed, and more than 300 dead were recovered up to the 4th inst. It is calculated that 10,000 head of cattle were killed. Besides this, five churches, five convents and hospitals, the town-hall, the prisons, baths, and theatre were destroyed, and 7000 people rendered homeless. On the 5th a sharp shock occurred at Granada a few minutes after 6 in the evening, and some slight shocks were felt at Malaga.

AT the Royal Institution, Prof. H. N. Moseley will, on Tuesday next (January 13), begin a course of five lectures on "Colonial Animals, their Structure and Life Histories"; Prof. Dewar will, on Thursday (January 15), begin a course of eleven lectures on "The New Chemistry"; and Dr. Waldstein will, on Saturday (January 17), begin a course of three lectures on "Greek Sculpture from Pheidias to the Roman Era." The Friday evening meetings will begin on January 16, when Prof. Tyndall will give a discourse on "Living Contagia."

ACCORDING to the *North China Herald* there died a few months ago at Pekin, the greatest Chinese mathematician of the present century. His name was Li Shan-lan, and he was Professor of Mathematics at the Foreign College in the Chinese Capital. He differed from the mathematicians of Europe in this respect, that he denied the non-existence of a point. "A point," said Prof. Li, "is an infinitesimally small cube," and in saying this he only reproduced the theories of Chinese sophists 2000 years ago. A great writer of that age put into the mouth of a sophistical being, whom he called the god of the northern sea, the following theory, which has its bearing on Prof. Li's heterodox views about a mathematical point: Subtlety is the occult part of the minute. Be a thing subtle or gross, it seems to me that it must have a form. A formless or unsubstantial thing cannot be distinguished as gross or subtle, discriminate as minutely as you will. What can be spoken of is the gross or palpable part of an entity; what can be imagined only is its subtle part or essence; but I take it that what is neither gross nor subtle can neither be talked of nor imagined.

M. LAUTH, the superintendent of the porcelain factory at Sèvres, is said to have discovered a new porcelain, which is far superior to the famous old Sèvres. After ten years' experiment and investigation he thinks he has produced a porcelain identical with that of China. Not only does it lend itself to artistic decoration, but it takes all kinds of glazes, and surpasses in beauty the colours obtained in China.

A PROPOSITION to connect Sicily with the mainland, by a submarine railway from Messina to Reggio, has been made by the Society of Engineering of Venice. It has been laid before the Minister of Public Works, who has referred it to a technical commission. A project by the French engineer who constructed the first railways in Rome to build a suspension bridge across the Straits of Messina, was laid at the time before Francis II.; but Garibaldi's campaign in Sicily, and the subsequent political events, caused it to be put aside.

WE learn from an Adelaide paper of November 3, 1884, that Mr. Clement L. Wragge has now extended his plan of operations on Mount Lofty, and has established, as a further experiment, a substantially equipped meteorological observatory there. At the Torrens Observatory readings are taken in direct connection with the observations on the Mount, 2350 feet.

PROF. SYLVESTER asks us to state that in his article "On the Genesis of an Idea," the footnote on p. 36, left-hand column, should read:—"It is one of Descartes' 'self-evident primary truths' that nothing which has happened could not have happened or have happened otherwise." The words "have happened" unfortunately dropped out.

THE additions to the Zoological Society's Gardens during the past week include a Vervet Monkey (*Cercopithecus lalandii* ♂) from South Africa, presented by Mr. J. W. Moon; a Bonnet Monkey (*Macacus sinicus* ♀) from India, presented by Mrs. M. E. Mackern; a Brown Hyæna (*Hyæna brunnea*) from South Africa, presented by Mr. R. W. Murray; a Nubian Ibex (*Capra nubiana* ♂), a —— Ibex (*Capra* —— ♂), a Domestic Goat (*Capra hircus* ♀) from the Soudan, presented by Mrs. Laing; seven Angulated Tortoises (*Chersina angulata*), two Hoary Snakes (*Coronella cana*), a Many-spotted Snake (*Coronella multimaculata*), a Robben Island Snake (*Coronella phocarum*) from South Africa, presented by the Rev. G. H. R. Fisk, C.M.Z.S.; a Golden Eagle (*Aquila chrysaetos*), European, deposited; a —— Gibbon (*Hylobates* ——) from Siam, purchased.

OUR ASTRONOMICAL COLUMN

THE TOTAL SOLAR ECLIPSE OF 1914, AUGUST 20–21.—There have been given in this column, at various times, particulars of the track of the central line in a number of the total eclipses of the sun that will occur during the next thirty years. To these may be added similar notes on the eclipse of August 20–21, 1914, which is a return of that of July 29, 1878, so extensively observed in the United States. The elements of this eclipse are very approximately as follow :—

G.M.T. of Conjunction in R.A. 1914, August 20, 23h. 55m. 3s.

R.A.		149 45	36·1
Moon's hourly motion in R.A. ...		33	7·5
Sun's ,, ,, ...		2	18·9
Moon's declination		13 9	42·2 N.
Sun's ,, ...		12 19	29·1 N.
Moon's hourly motion in declination		15	16·0 S.
Sun's ,, ,, ,, ...			49·7 S.
Moon's horizontal parallax		59	17·6
Sun's ,, ,, ...			8·7
Moon's geocentric semi-diameter ...		16	11·0
Sun's ,, ,, ,, ...		15	51·1

Hence it will be found that the

Total eclipse begins in long.	120 42 W.,	lat.	71 21 N.
,, ,, at oh. ,,	2 10 E. ,,		70 42 N.
,, ,, ends ,,	70 26 E. ,,		23 52 N.

In traversing the European continent, the central line runs through the points

Long.	Lat.	Long.	Lat.
12 33 E. ...	65 48 N.	30 33 E. ...	50 35 N.
14 39 ,, ...	64 32 ,,	32 53 ,, ...	48 2 ,,
22 44 ,, ...	58 23 ,,	39 12 ,, ...	41 23 ,,
27 30 ,, ...	53 48 ,,	46 28 ,, ...	34 52 ,,

The first of these points is close upon the coast of Norway, at the Island of Alstahoug, and on making a direct calculation for it, the totality is found to commence at oh. 54m. 19s. local mean time, continuing 1m. 59s., with the sun at an altitude of 37°, and this will be about the most favourable position for observation.

THE MINOR PLANETS.—That part of the *Berliner Astronomisches Jahrbuch* for 1887, containing its speciality, the ephemerides of the small planets for 1885, has been issued in advance of the publication of the volume. There are approximate places for every twentieth day of 237 out of the 244 now known, with accurately calculated opposition-ephemerides of 19. The most reliable elements of the orbits of these bodies to No. 237 inclusive are appended. *Ekkya* continues at a distance of less than 1·0 from the earth until February 11, and if the orbit had been more closely determined, would have afforded a favourable opportunity of applying the method of finding the solar parallax suggested by Prof. Galle, as the planet has been a ninth magnitude at this opposition. *Eva*, *Stephania*, and *Agathe*, also approach the earth during the present year, within her mean distance from the sun ; on August 10 *Stephania* will be at a distance of only 0·76, magnitude 11·1.

Ekkya has the least perihelion distance of the group, 1·604, while *Andromache*, with a considerable excentricity, has the greatest aphelion distance, 4·726, so that the orbits of the 244 planets extend over a space of 3·122, the earth's mean distance from the sun being taken as unity. The longest period of revolution occurs in the case of *Hilda* ; it is yet doubtful which has the shortest period ; No. 149 *Medusa* is credited with it at present, but until this member of the group has been re-observed, the point is perhaps doubtful. The most recently detected planet appears to have the shortest revolution next to *Medusa*, judging from the elements in the last circular of the *Berliner Jahrbuch*.

THE BRIGHTNESS OF SATURN.—Dr. G. Müller, of the Observatory at Potsdam, notifies in a recent number of the *Astronomische Nachrichten*, that since the year 1878 he has made regular photometric observations on Saturn, the main result of which he states to be, that when the earth is at an elevation of 26° above the plane of the ring, the planet's light is 2·4 times greater than when the earth is in that plane, or, in other words, that the brightness of Saturn's rings, when the earth is 26° from their plane, amounts to 58·3 per cent. of the brightness of the whole Saturnian system.

ENCKE'S COMET.—This comet appears to have been re observed both in Europe and the United States ; a somewha doubtful observation by Dr. Temped at Florence shows that th predicted elements will require probably but small correctio taking aberration into account, the calculated position o December 13 differed from that observed, + 1′·1 in right a cension, and + 1′·2 in declination ; the theoretical intensity light on this date was 0·193. In 1852, when the perihelio passage occurred a week only later than in the present year, th comet was first observed on January 9, the intensity of ligh being 0·228.

GEOGRAPHICAL NOTES

THE lectures given under the auspices of the Paris Geograph cal Society last spring were so successful, that they are to resumed this year. The first will be given by M. Janssen, January 13, on the universal meridian. The others will be, Prof. de Lapparent, on January 27, on the formation and dev lopment of the earth's crust ; February 3, M. Bouquet de Grye, the oceans ; February 10, Dr. Hamy, man ; March M. Himly, the conquest of the globe ; March 10, M. Levasse the riches of the globe ; March 24, M. Louis Simonin, t great lines of navigation ; March 31, M. Michel, railways a their relation to geography. These lectures are not free ev to members, the charge for the course to such being fifte francs, and twenty francs to outsiders. Some of the lectu will be illustrated with projections on the screen, and t success of the enterprise is so assured that a third series h already been arranged for in 1886.

MR. H. H. JOHNSTON writes as follows to the *Times* "The Kilimanjaro Expedition which I have just undertaken h resulted in a pleasant and healthy sojourn in one of the m beautiful and interesting regions in the world. I arrived at t mountain in the beginning of June, and settled first in M dara's territory, on the southern slopes. Here I built a sm town of about twenty houses and passed four months in colle ing and making numberless excursions right and left. T climate was that of a Devonshire summer, provisions w abundant, cheap, and of great variety, and I was only fea lest this delightful region might become to me a Capua, deter me from the more important work that awaited me a higher level than could be attained within the limits of M dara's kingdom. Accordingly, when I had received from coast a reinforcement of hardier men, I established myself height of 11,000 feet, and here built an even larger village t my settlement at Moshi. This was on a splendid site, mountain torrent dashed past our circle of pretty thatc cottages, which surmounted a grassy knoll above the stre to the south of us spread a wondrous prospect of sun-lit pl and distant rivers—a veritable map of Eastern Africa—ac the north rose the unspeakably grand summits of the moun mass—Kibo, a dazzling dome of virgin white, and Kimaw a piebald peak of black, jagged rocks, seamed and flecked snow. From this settlement I constantly ascended as far was able in one day's journey, but the difficulties which la the way of a complete ascent of either peak arose from the possibility of inducing any of my followers to accompany beyond 14,000 feet, for above this altitude they suffere keenly from cold and mountain sickness that no persuasi bribes would induce them to ascend any higher, far less to any of my *impedimenta*. Consequently, I could never beyond a certain distance from the settlement, the not permitting me to risk the chance of being benig in the snow. I reached, however, an altitude of 16 feet, a little more than 2000 feet from the summit of K (18,800 feet high). I found warm springs at 14,400 detected no signs of glacial action, and was somewhat d pointed with the paucity of plants growing at the snow fluids were very rare above 10,000 feet, and very abundant be Lizards and chameleons existed (and frogs also) up to the snow. Hyraxes (the hyrax is the coney of Scripture) common between 8000 and 13,000 feet, and I fancy are v sented by a new species. Buffaloes and elephants ascend 14,000 feet. The thunderstorms that frequently rage roun upper slopes of the mountain are terrific, and the wind at is so violent that no one can keep their feet. The natives

inhabit Kilimanjaro up to 6000 feet, are fairly tractable, and have a passionate love of trade, which with them is the great pacifier. They go absolutely naked, or if any clothing is worn in the way of ornament it rarely goes beyond leather capes for the shoulders. They all speak dialects belonging to the great Bantu group of languages. I have studied carefully several of them, and have, I believe, discovered some most interesting points in their construction likely to throw considerable light on the archaic forms of Bantu prefixes. I may add that, after a very happy sojourn in the lovely forest region of Tavcita at the foot of the mountain, I was compelled to return most reluctantly to the coast at the end of November owing to the exhaustion of my funds. I left Kilimanjaro with great regret, and on my homeward journey my thoughts were persistently directed to my whilom African home, rather than to an unwilling and too early return to civilisation. My collections have safely reached this country, and will, I hope, be sufficient to indicate the true character and relationships of the fauna and flora of Kilimanjaro."

THE death is announced at Lübeck of Dr. Robert Avé-Lallemant, at one time a well-known traveller in South America. He became surgeon to the Novara expedition, which, however, he left at Rio, in order to devote himself to exploration in Brazil. In 1858 he went to Rio Grande do Sul, where he commenced his journey into Southern Brazil, during which he visited Bonpland, a few months before his death, in his lonely ranche in Paraguay. He crossed the Uruguay Allegrette, San Gabriel, and Cacupava to the Jacuy. From San José he went along the coast to Laguna, visited the sources of the Uruguay, and returned to San José through forests still unknown to travellers. This journey lasted about a year, and soon after his return he again set out to travel through the northern provinces. Landing at Bahia, he followed the coast to the Mucury river. Here he discovered the shocking condition of some of the German colonies. Thence he went to Pernambuco, and ascended the Amazon to Tabatinga, on the Peruvian frontier. On these journeys he published two large works ("Reise durch Süd Brasilien, 1859," and a similar work on North Brazil), and numerous smaller ones. They give no new geographical discoveries or exact measurements, or the results of scientific investigation, but they contain valuable information respecting the country, the fauna and flora, and condition of the people. The later years of his life were spent in medical practice in his native city.

ACCORDING to *L'Exploration*, the Argentine authorities are sending an expedition to the Chaco. It consists of 200 men, divided into three columns, operating from different points, but meeting at Cangayé, a centre almost equally distant from Salta and Paraguay. The object is both military and scientific. It is desired to secure the possession of this vast territory to the Argentine Republic against the Indians, who are again masters there. Six topographical commissions are attached to the expedition in order to study the country, prepare maps, and also, it is said, to investigate the possibility of a railway as far as Oran, in the province of Salta. The investigation of the rivers, for which the gunboat *Pilcomayo* is sent, has been delayed by the low state of the water, but recent rains will now enable that work to be proceeded with. If the result should be the demonstration of the suitability of the *Pilcomayo* to navigation, not only will a great service be rendered to topographical science, but by assuring communications between Bolivia and the Rio Paraguay, a great economical revolution will, it is expected, be produced in these regions.

EXPERIMENTS SUITABLE FOR ILLUSTRATING ELEMENTARY INSTRUCTION IN CHEMISTRY

PROFESSORS SIR H. E. ROSCOE and W. J. Russell, by direction of the Lords of the Committee of Council on Education, have recently prepared, for the assistance of teachers of science schools and classes, an outline of experiments in chemistry. As this subject is now under discussion, we are glad to be able to give the outline *in extenso* in NATURE.

The notes have been prepared as some guide to the teachers as to the general character of the course of instruction expected in the elementary stage; they include instruction that should on no account be omitted, but must be considered rather as suggestive than exhaustive.

I.—*Combustion and Chemical Combination*

1. Burn a taper in a clean glass bottle. Show the presence of a colourless gas, differing in properties from common air by yielding a turbidity with lime-water.

2. Hold a bright glass over a burning candle and show the formation of water.

Explain what is meant by chemical change, and state that chemistry is an experimental science.

3. Make similar experiments with a petroleum or paraffin lamp.

4. Show that coal-gas also yields the same products by passing the products of combustion through lime-water and by collecting the water.

5. Explain the difference between mechanical mixture and chemical combination; and illustrate by a mixture of finely-divided copper and flour of sulphur, and the effect of heat upon the same.

6. Experiment to show that chemical change consists of a change in the properties of matter and that no loss of matter takes place. Suspend lamp chimney, partly filled with lumps of caustic soda, from the arm of a balance. Place short piece of candle in the lower part of the glass and counterbalance. Light the candle. Explain the increase in weight.

7. Heat is evolved when chemical combination takes place. Pour water on to quicklime. Refer also to experiments 1 and 3.

8. Combustibles and supporters of combustion. The purely relative character of these terms. Ordinary combustion the union of atmospheric oxygen with a body termed the combustible, or with one or more of its constituents, heat being developed, as in all cases where two or more bodies combine. Illustrate by showing that air will burn in coal-gas just as well as coal-gas will burn in air.

II.—*Air*

1. Existence of atmosphere, felt in winds.

2. Weight of air shown by means of a flask exhausted by the air-pump.

3. Burn phosphorus in air.

4. Burn phosphorus in confined volume of air and show diminution in bulk.

5. Show that some diminution takes place slowly when a stick of phosphorus is exposed to air at ordinary temperatures.

6. Test residual gas (N) with a burning taper.

7. Show that phosphorus burnt in air increases in weight.

8. Allow iron borings moistened with sal ammoniac to rust in a confined volume of air and introduce burning taper into residual gas (N).

9. Show that iron filings, suspended by a magnet hanging on one scale of a balance, increase in weight on heating.

10. Strongly heat the red substance which may be formed by gently heating mercury in the air. Collect and test the gas (O) with a glowing splinter of wood.

11. Add the gas thus obtained to the residue obtained in experiment 4 or 8 so as to make up the original volume of air, and show that a taper burns in this mixture as in common air.

12. Refer to numbers giving exact analysis of air, calling especial attention to the fact that it varies slightly in composition.

Also explain that no obvious change, such as increase of temperature or alteration of bulk, occurs when oxygen and nitrogen are mixed. Also that air has the properties of a mixture, and that when water is shaken up with air a portion of that air dissolves, the residue being found to contain relatively less oxygen than the original air, whilst the dissolved portion contains relatively more oxygen, and that this could not be the case if the air were a compound. Consequently it is a mixture and not a chemical compound.

13. It is important that these experiments should be made and their explanation given so as to teach the student how the composition of air is ascertained by experiment, and in a similar manner how oxygen was discovered by Priestley, and how the composition of the air and the part which oxygen plays in the phenomena of combustion were experimentally demonstrated by Lavoisier.

III.—*Effects of Animal and Vegetable Life upon the Atmosphere*

1. Show that by drawing air into the lungs through lime-water a very faint, if any, precipitate is produced; but that on expiring air from the lungs through another portion of lime-water a copious precipitate is soon formed.

2. Show the production of carbon dioxide by the oxidation of ordinary articles of food, as by heating small quantities of the dried substance, such as sugar, bread, or meat, with copper oxide.

3. Show that carbon dioxide exists in the air by pouring clear lime-water into a shallow vessel exposed to air, and explain that this small quantity of carbon dioxide serves as the main food of the plants that grow on the earth.

4. Expel air from water by boiling, and explain how fish and aquatic plants are thus provided with oxygen and carbonic acid.

5. Explain that plants eliminate and animals require oxygen. That animals take in oxygen from the air, and give out carbonic acid. That plants possess the power under the influence of light of assimilating carbon from carbon dioxide and liberating the oxygen. Explain that thus the balance of oxygen and carbon dioxide in the atmosphere is maintained.

6. Illustrate the action of plants by the formation of bubbles of oxygen when a fresh plant is exposed to the action of light in water containing carbonic acid in solution.

IV.—*Water*

1. Illustrate the three states of matter, the solid, the liquid, and the gaseous, with ice, water, and steam, and point out that the difference is caused by increase or diminution in the amount of heat present.

2. Composition of water. Decompose water by the electric current. Collect the two gases separately in a voltameter, and exhibit their properties.

3. Show formation of water by explosion of a mixture of hydrogen (two volumes) and oxygen (one volume) in a soda-water bottle.

4. Explode soap-bubbles inflated by a mixture of hydrogen and oxygen in the above proportions.

5. Throw potassium or sodium into water, and collect the hydrogen.

6. Pass steam over red-hot iron, collect the gas and show that it is hydrogen.

7. Show that the same gas may be obtained by dissolving zinc clippings or iron turnings in dilute sulphuric acid.

8. Demonstrate the properties of hydrogen:
   (*a*) Its combustibility.
   (*b*) Its lightness.
   (*c*) That a candle will not burn in it.
   (*d*) That water is formed when it burns in air.

9. Composition of water. Pass oxygen over red-hot copper, and show by weighing before and after that the weight increases.

10. Pass hydrogen over the copper oxide thus produced, heating gently. Collect the water, and show that the copper oxide has been entirely reduced, the tube weighing the same as before passing the oxygen through it.

11. Determine the composition of water by weight by passing dry hydrogen over half an ounce of copper oxide, and collecting the water in a weighed chloride of calcium tube. Show approximately that water contains two parts by weight of hydrogen to sixteen parts by weight of oxygen.

12. Note the first law of chemical combination: that chemical compounds, such as water, always contain their components in the same unvarying proportions.

13. Contrast the properties of water with those of its constituents on the one hand, and the properties of air with those of its constituents on the other.

14. Call attention to air and water as illustrations of the difference between a mixture and a compound, and quote oxygen, nitrogen, and hydrogen as examples of elementary bodies.

15. Separation of impurities from water by filtration and distillation. Preparation of fresh water from salt water.

16. Experiments illustrating solution and crystallisation. Soluble substances, as sugar, washing soda, alum; slightly soluble substances, as gypsum or plaster of Paris; insoluble substances, as chalk, flint, and sand.

17. Crystallise carbonate of soda, and sulphate of copper.

V.—*Oxygen and Ozone*

1. Prepare oxygen by heating
   (*a*) Oxide of mercury.
   (*b*) Potassium chlorate.
   (*c*) Mixture of potassium chlorate, and either manganese dioxide, copper oxide, or ferric oxide.

2. Show the re-ignition of a splinter of red-hot wood and glowing wick of taper.

3. Burn charcoal in oxygen, and show the formation of carbon dioxide.

4. Burn phosphorus simultaneously in air and in oxygen.

5. Burn watch-spring in oxygen.

6. Show that iron does not rust in dry oxygen.

7. *Ozone.*—Describe and demonstrate the formation of ozone by submitting oxygen to the silent electric discharge.

8. Describe and demonstrate the properties of ozone which distinguish it from ordinary oxygen, such as its action on metallic mercury, on indigo solution, or on potassium iodide and starch. Also its change to ordinary oxygen when passed through a heated glass tube.

9. Explain the difference in density between oxygen and ozone.

VI.—*Combining Weights; Names and Symbols of the Elements; Chemical Calculations, &c.*

1. Exhibit list of the elements, distinguishing (by means of the type) the non-metals from the metals; and, again, the more commonly occurring metals from those which are rarer.

2. Describe the occurrence of these elements in the air, in the sea, and in the solid crust of the earth.

3. Write up the results of the quantitative analysis of potassium chlorate. Explain that this is the result of experiment, and demonstrate the fact that, when heated, an unalterable weight of oxygen is given off and a given unalterable weight of potassium chloride remains behind.

4. Dissolve a crystal of pure chlorate of potassium, and the residue of chloride from heating chlorate, in two separate glasses, and show the difference in the reaction with silver chloride.

5. Explain the meaning of the term chemical symbol, and chemical formula of the salt, referring afterwards to the combining weights of the elements.

6. Explain the mode of determining the formula from the percentage composition.

7. Method of calculating the quantity of oxygen from potassium chlorate (and from manganese dioxide).

VII.—*Acids, Bases, and Salts*

1. Burn sodium in oxygen; dissolve the product in water, give the formula of the oxide. Express the action of water upon it by an equation.

2. Act on water with sodium, and collect the hydrogen. Explain by equation that the same substance, sodium hydrate or hydroxide, or caustic soda, is formed, as in experiment 1.

3. Burn sulphur in a current of oxygen, and show the pungent fumes slightly in the air. Explain that it is a mixture of sulphur dioxide and trioxide. Pass the gas thus obtained into water.

4. Add litmus solution to the solutions obtained in experiments 2 and 3, and show that on adding the one solution to the other the colour is changed, or a point is reached where a further addition of the one has no effect, whereas a minute addition of the other at once changes the colour. Explain the action by an equation.

5. Explain that the compound formed from the sodium oxide and water is termed an alkali, or alkaline or basic hydroxide, and the oxide from which it is formed an alkaline or basic oxide; that the compound formed from the sulphur dioxide and water is termed an acid hydroxide or acid, and the original oxide an acid forming oxide or anhydride.

6. Explain that sodium hydroxide and sulphurous acid may be taken as representative of the two classes into which hydroxides are divided.

7. Explain that by the action of the one upon the other a salt is formed. Exhibit a white crystalline salt, *e.g.* sodium sulphite.

VIII.—*Hydrogen*

1. Prepare hydrogen by the action of dilute sulphuric acid on zinc.

2. Show that it is not obtained by the use of pure zinc (amalgamated zinc is best used), and illustrate the effect of impurity by adding a drop or two of a lead or copper salt.

3. Prepare hydrogen by dissolving zinc or aluminium in sodium hydroxide.

4. Point out that whereas sodium displaces hydrogen from water at ordinary temperature, and that iron does so at a red heat, copper is without any action at any temperature.

5. Give equations for the various methods here indicated for obtaining hydrogen.

6. Explain fully in detail the methods of chemical calculation, and make the pupils thoroughly understand the methods of calculating quantities.

7. Demonstrate the physical properties of hydrogen, especially its lightness and diffusibility.

8. Compare the heating powers of jet of hydrogen burning in air and in oxygen. Explain the difference.

9. Describe and (if possible) demonstrate the construction and use of the oxy-hydrogen blowpipe.

10. Explain what is meant by heat of combustion, and define the term "heat-unit." Show for this purpose side by side 18 grammes of water and the quantity of water which would be raised 1° C. in temperature by the heat developed in the formation of this quantity of water from its elements.

11. Point out that hydrogen is a powerful reducing agent, illustrating this by the reduction of oxide of iron.

12. Show that nascent hydrogen, or hydrogen at the moment of its liberation from its compounds, frequently produces effects that hydrogen in the free state does not. Bubble hydrogen through ferric chloride solution and show that no discolorisation takes place. Place it in contact with zinc and dilute sulphuric acid and the colour disappears.

13. Explain the term nascent as applied to hydrogen and other gas at the moment of its liberation from one of its compounds, and distinguish between the atom of nascent hydrogen and the molecule of free hydrogen.

IX.—*Hydrochloric Acid and Chlorine*

1. Explain with equation and show the action of sulphuric acid on common salt. Collect the escaping gas by downward displacement and show its solubility in water.

2. Hold piece of paper dipped in ammonia solution in the gas.

3. Saturate water with the gas, noting that its volume increases and that considerable heat is developed.

4. Exhibit the effects produced by adding the solution to litmus and to silver nitrate solution.

5. Show that it has no action on indigo, or on a mixture of potassium iodide and starch solution.

6. Pass the gas over red-hot iron and show the production of hydrogen.

7. *Chlorine.*—Heat oxide of manganese with the solution of hydrochloric acid obtained in experiment 3, and collect several jars of the escaping chlorine by downward displacement. Give the equation.

8. Pass some of the gas into water. Exhibit the yellow colour of the solution and show that it precipitates silver nitrate and bleaches litmus and indigo.

9. Burn a jet of hydrogen in chlorine. Show the disappearance of the yellow-coloured gas.

10. Moisten some paper with a few drops of turpentine and throw it into a jar of chlorine. Point out the formation of hydrochloric acid and the deposition of carbon.

11. Explode a mixture of equal volumes of hydrogen and chlorine.

12. Point out how these experiments show that the gas produced in experiment 1 is a compound of chlorine and hydrogen. Give the symbol and atomic weight of chlorine, and state the composition of hydrochloric acid gas by weight and volume.

13. Explain the production of chlorine from common salt, sulphuric acid, and manganese dioxide. Give equations, and instruct the students in the calculations of quantities.

14. Show the combustion in chlorine, of phosphorus, antimony, and copper, and demonstrate its power to displace bromine and iodine from their compounds with metals.

15. Electrolysis of hydrochloric acid solution, and explain the nature of the evolution of equal volumes of its constituent gases.

16. Explain the bleaching action of chlorine as being due to its readiness with which it combines with hydrogen and that it thus acts as an oxidising agent. In illustration of this, show that a piece of dry turkey red cloth when placed in dry chlorine is not bleached.

X.—*Nitrogen and Ammonia*

1. The production of nitrogen from the air and the examination of its properties may here be repeated.

2. Describe and (if possible) demonstrate the production of ammonia by passing sparks from an induction coil or electric machine through a mixture of nitrogen and hydrogen. Explain that the reaction is not complete unless the ammonia is withdrawn as it is formed, owing to the fact that ammonia is readily decomposed by heat.

3. Prepare ammonia by heating an ammoniacal salt with slaked lime. Collect by upward displacement and over mercury, and show extreme solubility in water.

4. Demonstrate and explain its combination with hydrochloric acid, and show the volatility of sal ammoniac.

5. Show that the aqueous solution of ammonia behaves in the same way as a solution of sodium hydroxide, turning red litmus blue, neutralising acids, and forming precipitates in solutions of metals (copper, iron, and zinc salts, for example) of the same composition as those produced by sodium hydroxide. Explain that on this account it is considered that the ammonia solution contains ammonium hydroxide.

6. Pass dry ammonia gas over red-hot copper oxide and show the production of water and metallic copper.

7. Pass air and ammonia gas simultaneously over red-hot copper as a method of preparing nitrogen.

XI.—*Nitric Acid and the Oxides of Nitrogen*

1. Explain on the blackboard the composition by weight of the five distinct oxides of nitrogen as illustrative of the law of chemical combination in multiple proportions, and as a deduction from this, explain Dalton's atomic theory and state clearly what is meant by an atom. Demonstrate with a series of blocks labelled with the symbols of the different elements how this explains the observed facts of combination in multiple proportions.

2. Make clear to the student the difference between atom and molecule, and explain atomic weight and molecular weight of (1) hydrogen; (2) oxygen, ozone; (3) chlorine; and then of compounds such as (4) hydrochloric acid; (5) water; (6) ammonia.

3. Describe and (if possible) demonstrate the formation of the red fumes of nitric peroxide on passing an electric spark through air.

4. Preparation of nitric acid from nitre and sulphuric acid. Explain the reaction by an equation.

5. Calculation of quantities to be carefully gone into.

6. Exhibit nitre, nitrate of soda, sulphate and bisulphate of potash, and sulphate and bisulphate of soda.

7. Show the oxidising action of nitric acid by dropping it on to some red-hot charcoal.

8. Oxidising action of nitric acid on metallic tin and metallic copper.

8A. Deflagrate mixture of nitre and charcoal.

9. Show the decomposition of nitric acid when heated by dropping it into the bowl of a clay tobacco pipe, the stem of which is strongly heated, collecting the gas over water and testing with a flaming splinter of wood.

10. Heat potassium nitrate and collect the gas (O).

11. Prepare nitric oxide from residue in experiment 10 by treating with dilute sulphuric acid. Explain decomposition o nitrous acid into nitric oxide and nitric acid.

12. Prepare nitric oxide by action of nitric acid on copper turnings. Collect the gas. Explain the reaction.

13. Exhibit the direct combination of nitric oxide with oxygen. Note the formation of red fumes of nitrogen peroxide and their immediate absorption by water.

14. Show that flame of a taper is extinguished in nitric oxide, and that feebly burning phosphorus is also extinguished, but that brightly burning phosphorus continues to burn, and with greater brilliance than in ordinary air. Explain this.

15. Preparation of nitrous oxide. Neutralise nitric acid with ammonia. Evaporate the solution and obtain the solid salt. Show the preparation of nitrous oxide with this residue. Collect the gas over warm water. Give equation. Explain that nitrous oxide is readily soluble in cold water.

16. Show that like oxygen, nitrous oxide supports the combustion of a taper, and explain that this is caused by the decomposition of the gas, and the union of the constituents of the taper with the oxygen of the nitrous oxide, and liberation of the nitrogen.

17. Also show that phosphorus and strongly ignited sulphur burn in the gas, but that feebly ignited sulphur is extinguished. Explain this.

18. Point out the distinction between nitrous oxide and oxygen: (1) the solubility of nitrous oxide in cold water, (2) the production of nitrogen when bodies burn in it, (3) the fact that nitric oxide does not produce with it red fumes, as is the case with oxygen.

19. Prepare nitrogen from ammonium nitrite (*i.e.* a mixture of potassium nitrite and ammonium chloride).

20. Explain how, in the above experiments, the gradual deoxidation of nitric acid yields the several oxides of nitrogen, and lastly, nitrogen itself.

XII.—*Sulphur*

1. Exhibit the different forms of sulphur: flour of sulphur, brimstone or stick sulphur, and crystallised native sulphur.

2. Dissolve sulphur in bisulphide of carbon, and obtain crystals by spontaneous evaporation. Indicate the identity of this form with the naturally occurring crystals, and its difference from that obtained by fusing sulphur and allowing the mass to cool.

3. Explain what is meant by allotropic modification, and point out how the one form of crystal passes into the other.

4. Show the effect of heat upon sulphur melted in a flask. Contrast the brittle mass derived from cooling the sulphur after heating slightly above its melting-point by pouring into cold water, with the plastic mass obtained when cooled in the same way from a high temperature. Point out the changes which occur as the temperature rises, and exhibit the red vapour of sulphur.

5. Show combustion in sulphur vapour. Insert a coil of copper wire into the sulphur vapour, and show that combination occurs.

6. Distil sulphur in a small retort.

7. Pass hydrogen through boiling sulphur, and demonstrate the formation of hydrogen sulphide by its blackening action on lead paper.

8. Exhibit ferrous sulphide and galena (lead sulphide). Prepare hydrogen sulphide (sulphuretted hydrogen) from the former by the action of dilute sulphuric acid. Collect by displacement and prepare a solution of the gas in water.

9. Show the combustible nature of hydrogen sulphide by burning a jar of the gas, and point out the deposition of sulphur due to incomplete combustion. Demonstrate and explain the decomposition of hydrogen sulphide by chlorine, and show the deposition of sulphur when its solution is allowed to stand exposed to the air and light.

10. Demonstrate the value of hydrogen sulphide as a means of separating the metals into groups, by adding the solution or passing the gas into solutions of the various metals, as, for example, arsenious acid, copper sulphate, lead nitrate, antimony chloride, zinc sulphate, ferrous sulphate, and magnesium sulphate.

Write down the equations in each case.

11. Prepare sulphur dioxide by heating copper with sulphuric acid and collect the gas.

12. Illustrate the condensation of a gas into a liquid by passing sulphur dioxide into a glass tube surrounded by a freezing mixture of ice and salt.

13. Pass the gas into water and demonstrate the acid properties of the solution.

14. Prepare sulphur trioxide from fuming Nordhausen sulphuric acid. Add it to water and compare its behaviour with that of the dioxide under similar circumstances.

15. Describe the formation in the above experiment of sulphuric acid, explain the properties of oil of vitriol, demonstrating its affinity for water as exhibited by the great heat evolved when the two liquids are mixed.

16. Explain the barium chloride test for sulphuric acid.

17. Add barium chloride to a solution of sulphurous acid, and then nitric acid.

18. Explain that in consequence of the readiness with which sulphurous acid takes up oxygen it acts as a bleaching agent and as a powerful reducing agent.

XIII.—*Carbon*

1. Show the presence of carbon (charcoal) in wood by carbonising a splinter of wood in a test-tube; and in white sugar by pouring strong sulphuric acid on to a syrupy solution.

2. Describe the properties and modes of occurrence of the three allotropic modifications of carbon: (*a*) the amorphous form (lamp-black and charcoal), and the two crystalline forms, (*b*) graphite, and (*c*) diamond. Describe the octahedral forms of the crystal of diamond and show glass or wood models.

3. Explain that the same weight of each of these substances when burnt gives the same weight of the same product (carbon dioxide).

4. Calculate the weight of carbon dioxide obtained from given weight of any one of these forms.

5. Prepare carbon dioxide by treating chalk or carbonate soda (washing soda) with an acid. Prove that the gas th obtained really obtains carbon by heating a pellet of potassiu in the dry gas contained in a small flask.

6. Demonstrate the high specific gravity of carbon dioxide pouring it from one vessel to another, and showing that extinguishes a taper.

7. Pass carbon dioxide over red-hot carbon in an iron tub and show that it loses a part of its oxygen and is converted in carbon monoxide, a combustible gas, which, on combustio again yields carbon dioxide. Collect the carbon monoxide ov water containing caustic soda, and show that the gas does n render lime-water turbid. Then burn it, and show that i residual gas does possess this power.

8. Pass carbon monoxide over red-hot copper oxide to sh the formation of carbon dioxide, and explain the use of carb monoxide as a reducing agent in metallurgical operations.

9. Explain the changes which take place in an ordinary c fire. Mention the poisonous nature of the carbon monoxi and state that it is formed in cases of incomplete combustion fr insufficient supply of oxygen.

10. Mention heat of combustion of carbon, and of carb monoxide, and explain the value of the latter as a fuel.

11. Explain the reaction which takes place when carb dioxide is passed into caustic soda and into lime-water, a explain the formation of a soluble carbonate in the first, and insoluble carbonate in the second case.

CHARACTERISTICS OF THE NORTH AMERICAN FLORA[1]

WHEN the British Association, with much painstakin honours and gratifies the cultivators of science on this s of the ocean by meeting on American soil, it is but seemly tha Corresponding Member for the third of a century sho endeavour to manifest his interest in the occasion and to ren some service, if he can, to his fellow-naturalists in Section I would attempt to do so by pointing out, in a general w some of the characteristic features of the vegetation of country which they have come to visit,—a country of "m nificent distances," but of which some vistas may be had those who can use the facilities which are offered for enjoy them. Even to those who cannot command the time for dis excursions, and to some who may know little or nothin botany, the sketch which I offer may not be altogether unin esting. But I naturally address myself to the botanists of Association, to those who, having crossed the wide Atlantic, now invited to proceed westward over an almost equal bre of land; some, indeed, have already journeyed to the Pa coast, and have returned; and not a few, it is hoped, may ac the invitation to Philadelphia, where a warm welcome aw them—warmth of hospitality, rather than of summer tempera let us hope; but Philadelphia is proverbial for both. T opportunities may be afforded for a passing acquaintance the botany of the Atlantic border of the United State company with the botanists of the American Association, are expected to muster in full force.

What may be asked of me, then, is to portray certain out of the vegetation of the United States and the Cana Dominion, as contrasted with that of Europe; perhaps al touch upon the causes or anterior conditions to which mu the actual differences between the two floras may be asce For indeed, however interesting or curious the facts of the may be in themselves, they become far more instructive we attain to some clear conception of the dependent relati the present vegetation to a preceding state of things, o which it has come.

As to the Atlantic border on which we stand, probably first impression made upon the botanist or other observer co from Great Britain to New England or Canadian shores, w the similarity of what he here finds with what he left be Among the trees the White Birch and the Chestnut w identified, if not as exactly the same, yet with only slight ences—differences which may be said to be no more essenti profound than those in accent and intonation between the E

[1] An Address to the Botanists of the British Association for the Ad ment of Science; read at Montreal to the Biological Section, Aug 1884, by Prof. Asa Gray.

speech and that of the "Americans." The differences between the Beeches and Larches of the two countries are a little more accentuated; and still more those of the Hornbeams, Elms, and the nearest resembling Oaks. And so of several other trees. Only as you proceed westward and southward will the differences overpower the similarities, which still are met with.

In the fields and along open roadsides the likeness seems to be greater. But much of this likeness is the unconscious work of man, rather than of Nature, the reason of which is not far to seek. This was a region of forest, upon which the aborigines, though they here and there opened patches of land for cultivation, had made no permanent encroachment. Not very much of the herbaceous or other low undergrowth of this forest could bear exposure to the fervid summer's sun; and the change was too abrupt for adaptive modification. The plains and prairies of the great Mississippi Valley were then too remote for their vegetation to compete for the vacancy which was made here when forest was changed to grain-fields and then to meadow and pasture. And so the vacancy came to be filled in a notable measure by agrestial plants from Europe, the seeds of which came in seed-grain, in the coats and fleece and in the imported fodder of cattle and sheep, and in the various but not always apparent ways in which agricultural and commercial people unwittingly convey the plants and animals of one country to another. So, while an agricultural people displaced the aborigines which the forest sheltered and nourished, the herbs, purposely or accidentally brought with them, took possession of the clearings, and prevailed more or less over the native and rightful heirs to the soil,—not enough to supplant them, indeed, but enough to impart a certain adventitious Old World aspect to the fields and other open grounds, as well as to the precincts of habitations. In spring-time you would have seen the fields of this district yellow with European Buttercups and Dandelions, and whitened with the Ox-eye Daisy, and at midsummer brightened by the cærulean blue of Chicory. I can hardly name any native herbs which *in the fields and at the season* can vie with these intruders in floral show. The common Barberry of the Old World is an early denizen of New England. The Old Mullein, of a wholly alien race, shoots up in every pasture and new clearing, accompanied by the common Thistle, while another imported Thistle, called in the States "the Canada Thistle," has become a veritable nuisance, at which much legislation has been levelled in vain.

According to tradition the wayside Plantain was called by the American Indian "White-Man's foot," from its springing up wherever that foot had been planted. But there is some reason for suspecting that the Indian's ancestors brought it to this country. Moreover there is another reason for surmising that the long-accepted tradition is factitious. For there was already in the country a native Plantain, so like *Plantago major* that the botanists have only of late distinguished it. (I acknowledge my share in the oversight.) Possibly, although the botanists were at fault, the aborigines may have known the difference. The cows are said to know it. For a brother botanist of long experience tells me that, where the two grow together, cows freely feed upon the undoubtedly native species, and leave the naturalised one untouched.

It has been maintained that the ruderal and agrestial Old World plants and weeds of cultivation displace the indigenous plants of newly-settled countries in virtue of a strength which they have developed through survival in the struggle of ages, under severe competition incident to their former migrations. And it does seem that most of the pertinacious weeds of the Old World which have been given to us may not be indigenous even to Europe, at least to Western Europe, but belong to campestrine and unwooded regions farther east; and that, following the movements of pastoral and agricultural people, they may have played somewhat the same part in the once forest-clad Western Europe as they have been playing here. But it is unnecessary to build much upon the possibly fallacious idea of increased strength gained by competition. Opportunity may count for more than exceptional vigour; and the cases in which foreign plants have shown such superiority are mainly those in which a forest-destroying people have brought upon newly-bared soil the seeds of an open-ground vegetation.

The one marked exception that I know of, the case of recent and abundant influx of this class of Old World plants into a naturally treeless region, supports the same conclusion. Our botanist, Mr. John Ball, has recently called attention to it. The pampas of South-Eastern South America beyond the Rio Colorado, lying between the same parallels of latitude in the south as Montreal and Philadelphia in the north, and with climate and probably soils fit to sustain a varied vegetation, and even a fair proportion of forest, are not only treeless, but excessively poor in their herbaceous flora. The district has had no trees since its comparatively recent elevation from the sea. As Mr. Darwin long ago intimated: "Trees are absent not because they cannot grow and thrive, but because the only country from which they could have been derived—tropical and sub-tropical South America—could not supply species to suit the soil and climate." And as to the herbaceous and frutescent species, to continue the extract from Mr. Ball's instructive paper recently published in the Linnean Society's *Journal*, "in a district raised from the sea during the latest geological period, and bounded on the west by a great mountain-range mainly clothed with an alpine flora requiring the protection of snow in winter, and on the north by a warm temperate region whose flora is mainly of modified sub-tropical origin—the only plants that could occupy the newly-formed region were the comparatively few which, though developed under very different conditions, were sufficiently tolerant of change to adapt themselves to the new environment. The flora is poor, not because the land cannot support a richer one, but because the only regions from which a large population could be derived are inhabited by races unfit for emigration."

Singularly enough, this deficiency of herbaceous plants is being supplied from Europe, and the in-comers are spreading with great rapidity; for lack of other forest material even apple-trees are running wild and forming extensive groves. Men and cattle are, as usual, the agents of dissemination. But colonising plants are filling, in this instance, a vacancy which was left by Nature, while ours was made by man. We may agree with Mr. Ball in the opinion that the rapidity with which the intrusive plants have spread in this part of South America "is to be accounted for, less by any special fitness of the immigrant species, than by the fact that the ground is to a great extent unoccupied."

The principle applies here also; and in general, that it is opportunity rather than specially acquired vigour that has given Old World weeds an advantage may be inferred from the behaviour of our weeds indigenous to the country, the plants of the unwooded districts—prairies or savannas west and south—which, now that the way is open, are coming in one by one into these eastern parts, extending their area continually, and holding their ground quite as pertinaciously as the immigrant denizens. Almost every year gives new examples of the immigration of campestrine western plants into the Eastern States. They are well up to the spirit of the age: they travel by railway. The seeds are transported, some in the coats of cattle and sheep on the way to market, others in the food which supports them on the journey, and many in a way which you might not suspect, until you consider that these great roads run east and west, that the prevalent winds are from the west, that a freight-train left unguarded was not long ago blown on for more than one hundred miles before it could be stopped, not altogether on down grades, and that the bared and mostly unkempt borders of these railways form capital seed-beds and nursery-grounds for such plants.

Returning now from this side-issue, let me advert to another and, I judge, a very pleasant experience which the botanist and the cultivator may have on first visiting the American shores. At almost every step he comes upon old acquaintances, upon shrubs and trees and flowering herbs, mostly peculiar to this country, but with which he is familiar in the grounds and gardens of his home. Great Britain is especially hospitable to American trees and shrubs. There those both of the eastern and western sides of our continent flourish side by side. Here they almost wholly refuse such association. But the most familiar and longest-established representatives of our flora (certain western annuals excepted) were drawn from the Atlantic coast. Among them are the Virginia Creeper or Ampelopsis, almost as commonly grown in Europe as here, and which, I think, displays its autumnal crimson as brightly there as along the borders of its native woods where you will everywhere meet with it; the Red and Sugar Maples, which give the notable autumnal glow to our northern woods, but rarely make much show in Europe, perhaps for lack of sharp contrast between summer and autumn; the ornamental Ericaceous shrubs, Kalmias, Azaleas, Rhododendrons, and the like, specially called American plants in England, although all the Rhododendr of the finer sort are half Asiatic, the hardy American spe

Japanese region, the climates and conditions of which are very similar; and that the fossilised representatives of many of them have been brought to light in the late Tertiary deposits of the Arctic zone wherever explored. In mentioning some of the genera of this category I include the Magnolias, although there are no nearly identical species, but there is a seemingly identical Liriodendron in China, and the Schizandras and Illiciums are divided between the two floras; and I put into the list Menispermum, of which the only other species is Eastern Siberian, and scarcely distinguishable from ours. When you call to mind the list of wholly extra-European types which are identically or approximately represented in the Eastern North American and the Eastern Asiatic temperate floras, such as Trautvetteria and Hydrastis in Ranunculaceæ; Caulophyllum, Diphylleia, Jeffersonia, and Podophyllum in Berberideæ; Brasenia and Nelumbium in Nymphæaceæ; Stylophorum in Papaveraceæ; Stewartia and Gordonia in Ternstromiaceæ; the equivalent species of Xanthoxylum, the equivalent and identical species of Rhus and of the poisonous species of Rhus (one, if not both, of which you may meet with in every botanical excursion, and with which it will be safer not to handle); the Horse-Chestnuts, or called Buckeyes; the Negundo, a peculiar offshoot of the Maple tribe; when you consider that almost every one of the whole Leguminous trees mentioned as characteristic of our flora is represented by a species in China or Manchuria or Japan, and so of some herbaceous Leguminosæ; when you remember that the peculiar small order of which Calycanthus is the principal type has its other representative in the same region; that the species of Philadelphus, of Hydrangea, of Deutzia, Astilbe, Hamamelis, Diervilla, Triosteum; Mitchella, which carpets the ground under evergreen woods; Chiogenes, trailing over the shaded bogs; Epigæa, choicest woodland flower of early spring; Elliottia; Shortia (the curious history of which I need not rehearse); Styrax of cognate species; Diospyros, the Asiatic representatives of which affect a warmer climate, Gelsemium, which, under the name of Jessamine, is a special pride of the Southern Atlantic States: Pyrularia and Buckleya, peculiar Santalaceous shrubs; Sassafras and Benzoin of the Laurel family; Planera and Maclura; Pachysandra of the Box tribe; the great development of the Juglandaceæ of which the sole representative in Europe probably was brought over into South-Eastern Europe in prehistoric times); our Hemlock-Spruces, Arbor-Vitæ, Chamæcyparis, Taxodium, and Torreya with their East Asian counterparts, the Roxburghiaceæ represented by Croomia—and I might much further extend and particularise the enumeration—you will have enough to make clear that the peculiarities of the one flora are the peculiarities of the other, and that the two are in striking contrast to the flora of Europe.

(*To be continued.*)

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, December 18, 1884.—Sir John Lubbock, Bart., F.R.S., President, in the chair.—The following gentlemen were elected Fellows of the Society:—Lieut.-Col. W. R. Prain, and Messrs. T. B. Blow, H. G. Greenish, A. G. Howard, J. Niceville, C. B. Plowright, and F. Shrivell.—Mr. H. Marsh showed roots of sugar-cane grown in Queensland; a plant appearing to him to possess two sorts, viz. ordinary woody fibrous roots and others of a special kind.—Mr. E. Alf. Cox exhibited a wild cat found dead in a trap in Ben-Armin Forest, Sutherlandshire, where they are still frequently met with.—Mr. W. H. Beeby called attention to examples of burr (*Sparganium*) obtained at Albury Ponds, Surrey, the plant being quite distinct from the other British species; he proposed for it the name of *S. neglectum*.—In illustration of ornithological notes, Mr. Thos. E. Gunn showed an interesting series in varied plumage of the somewhat rare British bird, the blue-throated warbler. The examples in question were procured by Mr. G. Power at Cley, on the Norfolk coast, in September, 1884. Mr. Gunn also exhibited an immature female little bittern, shot at Broxbourne Bridge, Herts, on October 15 in the same year; also a hybrid between a goldfinch and bullfinch, which showed the marked characteristics of both parents.—Attention was drawn to Mr. R. Morton Middleton's examples of varieties of Indian corn (*Zea mays*, L.) from the United States, Natal, and the borders of the River Danube. The specimens showed marked differences from each other in size, colour, form, and in ornamentation of the seeds.—Mr. Thiselton Dyer exhibited life-size photographs of cones of two species of *Encephalartus* from South Africa, viz. *E. longifolius* and *E. latifrons*, neither hitherto figured in European books. He also showed tubers of *Ullucus tuberosus* from Venezuela, which, though esteemed as an esculent in South America, proved inedible when grown at Kew.—A paper was read by Mr. Henry O. Forbes, on contrivances for insuring self-fertilisation in some tropical orchids. The author described in detail the structural peculiarities of certain Orchidaceæ which had been made the subject of study by him under favourable circumstances. He arrives at the conclusion that a number of orchids are not fertilised by insects, but are so constructed as to enable them to fertilise themselves. This paper was illustrated by diagrams referring more particularly to such forms as *Phajus Blumei*, *Spathoglottis plicata*, *Arundina speciosa*, *Eria javensis*, and others.—Prof. St. G. Mivart read a paper on the cerebral convolutions of the Carnivora and Pinnipedia, and wherein were described for the first time in detail the brains of *Nandinia*, *Galidia*, *Cryptoprocta*, *Bassaricyon* (from a cast of the skull), *Mellivora*, *Galictis*, and *Grisonia*. The author, confirming the views of previous observers, gave additional reasons for a three-fold division of the Carnivora into Cynoidea, Æluroidea, and Arctoidea, though he remarked that amongst the Æluroids the section of Viverrina formed a very distinct group, judged by the cerebral characters. He specially called attention to the universal tendency amongst the Arctoidea to the definition of a distinct and conspicuous lozenge-shaped patch of brain substance defined by the crucial and precrucial sulci. This condition, which he found in no single non-arctoid Carnivora, he also found in the brain of *Otaria Gillespii*, and afterwards in *Phoca vitulina*, where it is very small and much hidden. This fact he adduced as an important argument in favour of the view that the Pinnipedia were evolved from some Arctoid, probably Ursine, form of land Carnivora.—Mr. F. O. Bower read a paper on apospory in ferns. His microscopical investigations on the growth of sporophore generation to the prothallus without the intervention of spores but confirms the statements of Mr. Chas. T. Druery on *Athyrium Filix-fœmina*, var. *clarissima*, previously communicated to the Society. Mr. Bower, moreover, finds the case in point to hold good in certain other ferns, for example, *Polystichum angulare*, where there is the formation of an expansion of *undoubted prothalloid nature* bearing sexual organs by a process of purely vegetative outgrowth from the fern plant. That is, there is a transition from the sporophore generation to the oosphore by a vegetable growth, and without any connection either with spores or indeed with sporangia or sori. The author goes on to point out the bearing of these observations and cultures on the general life history of the fern, so far as the modifications of the genetic cycle are concerned; and he further compares this new phenomenon of "apospory" in ferns with similar cases in other plants, while insisting on the importance of the cases at issue.—A communication on the aërial and submerged leaves of *Ranunculus lingua*, L., was read by Mr. Freeman Roper. He shows from specimens obtained near Eastbourne that the two sets of leaves in question differ so materially from each other that they might not be suspected to belong to the same plant, the submerged being larger, broader, ovate or cordate, and possessing abundance of stomata.

Geological Society, December 14, 1884.—W. Carruthers, F.R.S., Vice-President, in the chair.—David Llewellin Evans was elected a Fellow of the Society.—The following communications were read:—On the south-western extension of the Clifton fault, by Prof. C. Lloyd Morgan, F.G.S., Assoc. R.S.M.—On the recent discovery of Pteraspidian fish in the Upper Silurian rocks of North America, by Prof. E. W. Claypole, B.A., B.Sc. Lond., F.G.S.—On some West-Indian phosphate deposits, by George Hughes, F.C.S. (Communicated by W. T. Blanford, LL.D., F.R.S., Sec.G.S.).—Notes on species of *Phyllopora* and *Thamniscus* from the Lower Silurian rocks near Welshpool, Wales, by George Robert Vine (Communicated by Prof. P. Martin Duncan, F.R.S., F.G.S.).

Victoria (Philosophical) Institute, January 5.—A paper on "The Religion of the Aboriginal Tribes of India," by Prof. Avery, was read. In it the author sketched the peculiarities of the beliefs of those tribes, so far as was known.

means of safe-guarding the long wire from differ-
temperature. Dr. Koenig and Dr. Richarz had now,
of each other, devised another method of utilising
for the purpose of determining the mean density
Instead of placing the lead ball 21 m. under the
they brought the heavy body directly under the
whence a line, passing through a perforation of the
bore the lower scale immediately underneath it.
Now, a body was weighed in the upper scale, the mass of
acted in a sense similar to that of the force of gravity, and
attraction was added to gravitation. When, on the other
hand, a body was weighed in the lower scale, the mass of
operated in an opposite direction, and its attraction was
subtracted from gravitation. By this experiment, therefore, a
double effect was obtained from the mass of lead instead of the
single effect in Herr von Jolly's experiment. Again, by
placing a second equally large mass of lead under the scale
on the other side, disposing it in the same manner as the first
mass, the effect of the mass of lead might be multiplied four-
fold. An equilibration might be made by placing the weight
on one side in the upper, on the other side in the lower,
scale. Then the weights might be transposed. Indepen-
dently of the advantage of a fourfold comparative estimate
of the attraction of the mass of lead, all disturbances due
to differences of temperature were by this method entirely
excluded. The precision of the measurement would be still
further enhanced by using a mass of lead of 2000 centner.
The total mass of lead would compose a block, the most suit-
able form for which had yet to be theoretically determined. In
the centre, above this block, would stand the balance, and the
wires of both scales would pass through two equal perforations
in the ends of which, under the block, would depend the two
outer scales. The construction of such a block of lead would
be rendered possible by making it consist of 1300 separate
pieces capable of being joined together into the form desired.
After a series of experiments they might be fitted up anew,
so as to secure compensation for any errors due to unequal in-
ternal structure of the blocks. Of these masses of lead a parel-
lelopiped would have a side of 2·5 m. and a height of 1·5 m.
It was self-evident, the precision of the balance was a matter
of supreme moment for these measurements. The mechanic
who had undertaken their construction had engaged to produce
a correctness of one-hundred millionth for the weight of 1 kg.
mass in such measurements. He had further engaged, by an
ingenious modification of the construction, to obviate the error
arising from the circumstance that the edges never corresponded
mathematically with that term, but had always more or less
obtuse, so that with the inclination of the beams the plane of
support changed. Dr. Koenig hoped to be able in the course
of the year to announce the numerical results of the experiment.

NEGRETTI AND ZAMBRA'S
CHRISTMAS PRESENTS.

USEFUL AND ORNAMENTAL.

LADIES' IVORY OPERA GLASS,
Gilt Mounted, with Engraved Monogram. Prices from £2 2s.
GENTLEMEN'S LEATHER-COVERED FIELD GLASS,
With Monogram in Pierced Silver. Price from £3 3s.
Opera Glasses mounted in Aluminium, Tortoiseshell, or Pearl. Microscopes, Magic Lanterns, &c., of every description.
Illustrated Price Lists posted free to all parts of the World.
NEGRETTI AND ZAMBRA,
SCIENTIFIC INSTRUMENT MAKERS AND OPTICIANS TO THE QUEEN,
HOLBORN VIADUCT.
Branches:—
45, Cornhill; 122, Regent Street; Photographic Studio, Crystal Palace.

UNIVERSITY COLLEGE, LONDON.

GEOLOGY and MINERALOGY.—Prof. BONNEY, D.Sc., F.R.S., Pres.G.S., will begin the following Courses of Lectures in JANUARY 1883:—

GEOLOGY (General Course; about 60 Lectures): Tuesdays, Wednesdays, Thursdays, at 10 (January 23).

CATECHETICAL LECTURES: Thursdays, at 10 (January 25).

MICROSCOPIC PETROLOGY: Thursdays at 11 (January 25).

ECONOMIC GEOLOGY (about 12 Lectures): Tuesdays at 11 (January 23).

TALFOURD ELY, Secretary.

LITHOGRAPHIC ILLUSTRATIONS

Of the highest class executed for Scientists in Entomology, Geology, Natural History, Antiquities, &c. Accurate Drawings made from Specimens either by the Microscope or in natural size.—W. PURKISS, 6, Featherstone Buildings, Holborn, W.C.

HOME TUITION, LONDON & SUBURBS.

—STUDENTS in Classics and Mathematics attended at their own homes by a High Wrangler, F.R.S., on very reasonable terms. Special attention to backward pupils.—X., 9, Dorville Crescent, Hammersmith.

G. CALVER has received HIGHEST

AWARD for "Excellence and Improvements" in Reflecting Telescopes exhibited at the International Exhibition, London.—Descriptive Catalogues, twelve stamps.

G. CALVER, F.R.A.S., Wilford, Chelmsford.

MINERALOGY AND GEOLOGY.

Mr. HENSON'S Latest Arrivals are:—

Very Fine DOUBLY-TERMINATED CRYSTALS of ZIRCON, ¾ inches long; 18 ounces; BERYLS, DIOPTASE, UWAROWITE, WAUTWITE, NATIVE SILVER, HERDERITE, VERY BRILLIANT RUTILES, CHALCOSIDERITE, and NATIVE COPPER, Cornwall; POLISHED JAUE and GREEN AVENTURINE, GROUPS and SINGLE CRYSTALS of STIBNITE, Japan; "SHERRY" COLOURED TOPAZES, Siberia.

A Large Series of ROCKS, also MICROSCOPIC SECTIONS of the same.

Lists on Application. Hammers, Chisels, and Hammer Straps.

PRIVATE LESSONS AND EVENING CLASSES.

BLOWPIPE CASES AND APPARATUS. Catalogues free.

SAMUEL HENSON,
277, STRAND, LONDON,
Opposite Norfolk Street.

LANTERN READINGS.—DISSOLVING VIEWS.

THE NEW QUADRUPLICON.

New Season, 1882 and 1883.—Popular Subjects for this Season.

The Channel Islands—The War in the Soudan—The River Thames—Devonshire Scenery—Hereford and the River Wye—The English Lakes—London Poor and How They Live—Egypt and the Nile Expedition—Norway—The Lifeboat—The Signal Box—The Maids of Lee—Poor Pa's Trousers—Shadows on the Blinds, &c.

The largest and newest Stock of Lanterns and Slides, Scientific and General, on Hire and Sale in this country at the Lowest Prices.

E. MARSHALL, 76, Queen Victoria Street, London, E.C.

NEW MICROSCOPIC SLIDES

JUST ISSUED BY

EDWARD WARD, 249, OXFORD STREET, MANCHESTER.

British Polyzoa (Polypidom of Bicellaria ciliata), Opaque for Binocular.
" " " Balsam for Polariscope.
Parasite of Ewe (Nemoa dromedarii), in Balsam.

Price One Shilling each, or post free for 14 Stamps each.

Microscopic Slides in great variety sent out on selection.

New Series of Dissected Objects, 12 Dissections of the Cockroach, post free for 20 stamps.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Diedrichsen, Hamburg, Alsterufer, 28. Edited by W. von FREDERSDORFF, M.R., Hamburg, Alexander Street, E.

On the 1st of every Month.

JOURNAL OF BOTANY,

BRITISH AND FOREIGN,

Edited by JAMES BRITTEN, F.L.S., British Museum.

CONTENTS:—Original Articles by leading Botanists.—Extracts, and Notices of Books and Memoirs.—Articles in Journals.—Botanical News.—Proceedings of Societies.

Price 2s. 6d. Subscription for One Year, payable in advance, 12s.

London: WEST, NEWMAN, & CO., 54, Hatton Garden, E.C.

LIVING SPECIMENS FOR THE MICROSCOP

GOLD MEDAL awarded at the FISHERIES EXHIBITION 1

THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHA

who has last week sent to his subscribers Clava squamata, with drawing description. He has also sent out Trout ova, Eurycercus lamellatus, Lo pus crystallinus, Spongilla fluviatilis, Melicerta ringens, Brachionus ang earus, Stentor polymorphus, Cordylophora lacustris; also Hydra, Anne Vortricella, Crayfish, and other Specimens for (Huxley and Martin's) Biol cal Laboratory work.

Weekly Announcements will be made in this place of Organisms I supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of Six Months for Subscription of £1 or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Ten Parts, 1s. each.

C. D. AHRENS,

PRISM WORKER AND PRACTICAL OPTICIA

36, GREAT RUSSELL STREET, LONDON, W.C

SPECIAL NOTICE—See the New Polarizing Prism.

Can be used over any A & B Eyepiece. Strongly recommended for La Work; will take in any Object. Also see the New Erecting Micros Any Object-Glass and any Eyepiece can be used with it. Is to the only of seeing the Objects in their right shape and form. Maker of the La Nicol Prisms in existence for the Late W. Spottiswoode, Esq., P.R.S., &c., and for Frank Crisp, Esq., LL.B., B.A., &c., &c.

WATSON'S PLANE and SOLID GEOMETRY. 3s. 6d.

A SHORT TEXT-BOOK of INORGANIC CHEMISTRY. By Dr. HERMANN KOLBE, Professor of Chemistry in the University of Leipzig. Translated and Edited from the Second German Edition by T. S. HUMPIDGE, Ph.D., B.Sc. (Lond.), Professor of Chemistry and Physics in the University College of Wales, Aberystwith. With a Coloured Table of Spectra and 66 Illustrations engraved on Wood. Crown 8vo, 7s. 6d.

GANOT'S ELEMENTARY TREATISE on PHYSICS, Experimental and Applied, for the Use of Colleges and Schools. Translated and Edited by E. ATKINSON, Ph.D., F.C.S., Professor of Experimental Science, Staff College, Sandhurst. Eleventh Edition, revised and enlarged; with 5 Coloured Plates and 898 Woodcuts. Large Crown 8vo. 15s.

GANOT'S NATURAL PHILOSOPHY for GENERAL READERS and YOUNG PERSONS. Translated and Edited by E. ATKINSON, Ph.D., F.C.S., Professor of Experimental Science, Staff College, Sandhurst. Fifth Edition; with 2 Coloured Plates and 495 Woodcuts. Crown 8vo. 7s. 6d.

PRINCIPLES of MECHANICS. By T. M. GOODEVE, M.A., Professor of Mechanics at the Royal School of Mines. New Edition, rewritten and enlarged; with 253 Diagrams and Figures engraved on Wood. Crown 8vo. 6s.

The ELEMENTS of MECHANISM. By T. M. GOODEVE, M.A., New Edition, rewritten and enlarged; with 342 Woodcuts. Crown 8vo. 6s.

PRACTICAL MECHANICS, an Elementary Introduction to their Study, Illustrated by numerous Examples. By the Rev. J. F. TWISDEN, M.A., Professor of Mathematics, Staff College, Sandhurst. Eighth Edition. Crown 8vo. 10s. 6d.

FIRST LESSONS in THEORETICAL MECHANICS. By the Rev. J. F. TWISDEN, M.A., Professor of Mathematics, Staff College, Sandhurst. Third Edition, revised; with 154 Diagrams. Crown 8vo. 8s. 6d.

LESSONS in ELEMENTARY MECHANICS, introductory to the Study of Physical Science. Designed for the Use of Schools, and of Candidates for the London Matriculation, and other Examinations; with numerous Examples and 124 Woodcuts. By P. MAGNUS, B.Sc., B.A. Tenth Edition. Fcap. 8vo. 3s. 6d.

WINTER'S GEOMETRICAL DRAWING. Part I., including Prac- tical Plane Geometry, the Construction of Scales, the Use of the Sector, the Marquois Scales, and the Protractor. Eleventh Edition, corrected and enlarged. Crown 8vo. 3s. 6d. PART II. The Practical Geometry of Planes and Solids. With nearly 300 Exercises. New Edition, revised and enlarged. Crown 8vo. 6s. 6d.

A TEXT-BOOK on PRACTICAL SOLID or DESCRIPTIVE GEO- METRY. By DAVID ALLAN LOW, Whitworth Scholar; Lecturer on Engineering in Allan Glen's Institution, Glasgow. In Two Parts. PART I. Crown 8vo. 2s. PART II. Crown 8vo. 3s.

NESBIT'S TREATISE on PRACTICAL MENSURATION: Augmented by a Concise Treatise on Levelling, a Builder's Dictionary of the Terms used in Architecture, and Questions for Examination. Illustrated by above 700 practical Examples and about 700 Woodcuts. Revised and Improved by the Rev. J. HUNTER, M.A. 12mo. 3s. 6d. KEY, 5s.

London: LONGMANS, GREEN, & CO., Paternoster Row.

Year-Book of the Scientific and Learned Societies of Great Britain and Ireland.

NOTICE.

SECRETARIES of SOCIETIES who have not yet returned SCHEDULE of PARTICULARS required for the forthcoming issue of the above Work, will greatly oblige by communicating at once with the PUBLISHERS.

CHARLES GRIFFIN & CO., EXETER STREET, STRAND, LONDON.

W. SWAN SONNENSCHEIN & CO.

ELEMENTARY TEXT-BOOK OF ZOOLOGY. By Prof. W. CLAUS. Edited by ADAM SEDGWICK, M.A., Fellow and Lecturer of Trinity College, Cambridge; assisted by F. G. HEATHCOTE, B.A., Trinity College, Cambridge. With 706 Illustrations. Demy 8vo.

SECTION 1.—General Part and Special Part—"Protozoa to Insecta." Now ready. 21s.

SECTION 2.—Special Part—"Mollusca to Man." In a few days.

Demy 8vo. 16s.

A BIBLIOGRAPHY, GUIDE, & INDEX TO CLIMATE. By ALEX. RAMSAY, F.G.S.

THE ROYAL RELIEF ATLAS OF ALL PARTS OF THE GLOBE. By J. PHILLIPS BEVAN, F.G.S., F.S.S. Consisting of 31 "Relief" (or Embossed) Maps, with descriptive Text facing each Map. Each Map is separately framed in cardboard mounts, and the whole handsomely bound in One Volume, half Persian gilt. Royal 4to. Price 21s. *[Second Edition now ready.*

"This Atlas measures about twelve inches by ten, and is so bound as to lie perfectly flat wherever opened. . . . Every one who wishes his children to understand physical geography should buy the 'Royal Relief Atlas.' It will come as a revelation to them."—*Teacher.*

Third Edition of

THE CRUISE OF THE "ALERT."

FOUR YEARS IN PATAGONIAN, POLYNESIAN, AND MASCARENE WATERS.

By R. W. COPPINGER, M.D. (Staff-Surgeon on board *Alert*).

With 16 Full-page Plates from Sketches and Photos by the AUTHOR and Mr. F. NORTH, R.N. Demy 8vo. Cloth extra. 7s. 6d.

"No one could be better fitted than Dr. Coppinger to put into a readable shape the result of his investigations as a naturalist and his impressions of strange scenery and savage men. . . . Every page attests his method and his practical familiarity with the fauna and flora of tropical and temperate climes. . . . The *Alert* did nothing in a hurry. Plenty of spare time was found for dredging and fishing with drift-nets and hand-lines, for dragging the tow-net when the ship was sailing, and for making excursions into regions rarely trodden except by Chilian traders and French adventurers."—*Saturday Review.*

W. SWAN SONNENSCHEIN & CO., Paternoster Square.

AUTHOR'S COMPLETE EDITION, REVISED BY TARN.

This Day, in one large 4to Volume, with 61 Plates, Portrait, and Numerous Woodcuts. Price £1 5s., Cloth, Bevelled.

TREDGOLD'S CARPENTRY—The ELE- MENTARY PRINCIPLES of CARPENTRY. By THOMAS TREDGOLD, C.E. With an Appendix of various Roofs of Iron and Stone. Sixth Edition, thoroughly Revised and considerably Enlarged, by E. WYNDHAM TARN, M.A., Architect.

CROSBY LOCKWOOD & CO., 7, Stationers'-Hall Court, London, E.C.

A NEW NOVEL.

CHARLEY KINGSTON'S AUNT: a Study of Medical Life and Experience. By PEN OLIVER, F.R.C.S. Crown 8vo. 6s.

Punch says:—

"Now, here is a tale I might tell you—but shan't,
Of one who grew rich by dissecting his Aunt!
I won't give the plot, but this much I may tell—
She certainly cut up uncommonly well!
Send off to Macmillan, and quickly read then
The story that's writ by Pen Oliver's pen."

A NEW STORY BY MRS. HUMPHRY WARD.

MISS BRETHERTON.

By Mrs. HUMPHRY WARD. Crown 8vo. 6s.

"Mrs. Ward has written a story especially distinguished for ease, purity, and effectiveness of style. The incidents are delicately and yet powerfully treated, and the book is well worth reading."—*Academy.*

MACMILLAN & CO., London.

Now Ready, with 4 Maps and 16 Illustrations. 8vo. 14s.

IN THE LENA DELTA.

A Narrative of the Search for Lieut.-Commander De Long and his Companions, followed by an Account of the Greely Relief Expedition, and a Proposed Method of Reaching the North Pole.

By GEORGE W. MELVILLE, Chief Engineer U.S.N.

Edited by MELVILLE PHILIPS.

London: LONGMANS, GREEN, & CO.

Now Ready, in Crown 8vo. Price 6s.

THURSDAY, JANUARY 15, 1885

THE EARTHQUAKES IN SPAIN

EVEN the most conservative believer in the stability of Mother Earth must by this time have had his faith sorely shaken. Year after year, and month after month, we receive tidings of more or less serious shakings, varying from slight movements, such as merely set bells ringing and disturb the crockery on kitchen-shelves, to such shocks as convulse wide districts and bring with them disaster to life and limb as well as destruction to property. As if these tangible proofs of insecurity were not enough, we have learnt further that what we have been in the habit of dignifying with the name of the "solid" earth is really in a state of perpetual tremor. The thud of falling rain-drops, the patter of birds' feet, the tread of cattle, the gambols of children, so affect the ground on which we walk that the vibrations which they cause in it can be made clearly audible by the microphone and visible by the galvanometer. The position of the sun in the sky, the rise and fall of the tides, the thermometrical and barometrical oscillations of the atmosphere, produce in the outer parts of the earth corresponding pulsations, which, though not always certainly referable to their originating source, are perfectly recognisable, and can be registered by sufficiently delicate instruments. So that, instead of being on the whole a motionless, inert mass, the land is, in its way, almost as restless as the sea.

Fortunately, we are not sensible of these daily and hourly vibrations. It is only from time to time, by the news of earthquake-shocks from different quarters of the globe, that our attention is vividly drawn to the subject, and we are made to realise how little right we have to count on the continued stability of our own district. The daily tidings from the south of Spain, coming after so many recent chronicles of earthquake disaster in Europe, cannot but recall our thoughts to this subject. When the peace and goodwill of Christmas-tide were once more brightening the close of the year all over Christendom, the inhabitants of a wide tract of Andalusia were suddenly thrown into consternation by a succession of powerful earthquakes. The district most severely visited lies in the province of Granada and Malaga, and forms a parallelogram measuring about 70 miles from east to west and about 35 from north to south. The eastern part of the affected district passes into the great range of the Sierra Nevada, of which the highest peaks rise between 11,000 and 12,000 feet above the sea. Westwards, this range throws off some minor spurs, particularly the Sierras Tejada and Alhama, which curve round towards the north-west. The chief mass of the Sierras consists of crystalline schists stretching east and west, and flanked with Tertiary strata, from beneath which various Jurassic and other Secondary rocks emerge. The area of maximum destruction appears to be among the Western Sierras, and on the ground to the south and north of them.

The greatest amount of damage has been done at Alhama, which is almost entirely ruined. This little town stands nearly on the junction of the Tertiary rocks with the schists that rise into the more rugged ground of the mountains. A little to the south-east Abunuelas has also suffered severely. From that central area the shocks seem to have lessened outwards, but to have been felt most along the northern and southern flanks of the Sierras. According to one account the shocks have indicated earth-waves from south to north, with return movements in the contrary direction. Not improbably the actual focus of disturbance lies along the axis of the Sierras Alhama and Tejada. But the shocks have been felt over a much wider area. They have extended along the line of the mountains at least as far as Gibraltar in the west, though they are not recorded as having been marked in an easterly direction. Northwards, the towns and villages lying nearest to the centre of commotion have suffered most—Antequera, Loja, Granada. But far beyond these districts, terror was occasioned to the people of Cordova, Cadiz, and Seville, and the first shock was felt even at Madrid. No sea-wave has been chronicled as having affected any part of the coast, whence we may reasonably conclude that the earthquakes have not originated under the sea.

The Spanish peninsula has long had an evil reputation for the frequency, destructiveness, and long continuance of its earthquakes. In the present case the shocks are said to have begun three days before Christmas; but the first destructive wave arose on Christmas day. Since that date there has been an almost daily continuance of shocks of varying intensity. Such was also the case in the summer of 1863 along the great range of Sierras from Malaga to Alicante, and still earlier, in 1849, the same district continued to vibrate for several months.

Unfortunately, no accurate registers have been kept of these earth-tremors. Observations on earthquake phenomena made after the event, though useful so far, are now recognised as altogether insufficient to enable us to solve the problems presented by this interesting, but difficult, branch of geological physics. The establishment of self-registering apparatus, which was temporarily assisted many years ago by the British Association in the case of the simple instruments set up at Comrie in Perthshire, and which, more perfectly developed in Italy, has recently been so well inaugurated in Japan by Profs. Milne and Ewing, is the only satisfactory method of accumulating the necessary data. Until facts thus chronicled have been patiently gathered for some years in regions widely separated from each other, alike in distance and in geological structure, seismology must be content to remain very much at a stand. Of course, speculation will be as rife as ever, but cautious men of science will probably withhold their judgment until they are in possession of data of a kind that has not yet been systematically observed and registered.

But even before these data are gathered for the region of Andalusia, we can hardly doubt that fundamentally the shocks so often felt there arise from the process of mountain-making. The vibrations are propagated along the Sierras, and are felt with most violence near their flanks. They are probably in some way connected with the movements of the terrestrial crust that first started and have successively upraised the parallel lines of mountainous ridge that diver surface of the Spanish tableland. Among the q

and at considerable length, in two papers read before the Royal Society in 1796 and 1798. He laid down the fundamental formula by which the length of the arm of the righting or upsetting couple may be determined for any angle of inclination of a ship; and he showed how the several terms contained in it may be calculated. Two of these terms, viz. the volumes of the wedges of immersion and emersion, and the positions of their centres of gravity, involved very lengthy and complicated calculations. The tediousness and complexity of stability investigations have been chiefly caused by the difficulties connected with finding by actual measurement and calculation the solid contents of these wedges and the positions of their centre of gravity.

Let Fig. 1 represent the transverse section of a ship, of which W L is the line in which the plane of flotation, when the ship is upright, is cut by the plane of the paper; the centre of gravity of the whole ship being at G. Let B similarly represent the centre of gravity of the volume of the ship's displacement, or centre of buoyancy, as it is commonly called. Now, suppose the ship to be inclined a few degrees by some external force that acts horizontally, and therefore does not alter the displacement; and let

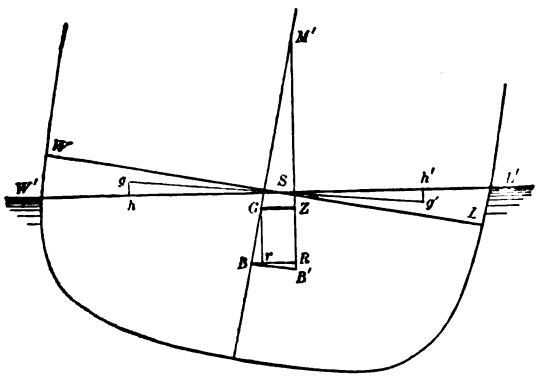

FIG. 1.

W' L' represent the new water-line. The effect of the inclination has obviously been to lift out of the water a wedge-shaped body, of which W S W' is the section, and to submerge on the opposite side of the ship another somewhat similar wedge-shaped body, of which the section is L S L'. These wedges are known as the wedges of immersion and emersion respectively. They are each bounded on the outside by the outside form of the ship, and will therefore usually differ in external form; but they must be precisely equal in volume, or otherwise the whole displacement of the ship could not remain unaltered.

The inclination of the ship through the angle W S W' has changed the position of the centre of buoyancy B to B'; and G Z is the length of the perpendicular let fall from G, the centre of gravity, upon the vertical B' M, through B'. G Z is the arm of the couple at the ends of which the weight of the ship and the upward pressure of the water act; and it is commonly called the righting arm. Atwood's fundamental formula for determining the length of the righting arm is—

$$GZ = v \times hh'/V - BG \sin\theta,$$

v being the volume of either of the wedges W S W', L' S L; hh' the distance, measured parallel to W' L', between g and g', the centres of gravity of these wedges; V the volume of the ship's displacement; and θ the angle of inclination W S W'.

It is obvious that the labour of calculating the volumes and positions of centres of gravity of such irregularly shaped bodies as the wedges of immersion and emersion must be very great. The labour and difficulty are further increased by the necessity of drawing the inclined water lines, such as W' L', in positions which give equal volumes for these wedges. The point S, where the inclined water-line intersects the upright water-line, thus requires to be determined separately for each angle of inclination. Atwood's manner of approximating to the volumes and moments of these wedges was simplified by Mr. S. Read. The method which has commonly been adopted in recent years is, however, one brought forward at the Institution of Naval Architects, by Mr. F. K. Barnes, in 1861.

The old systems of stability calculation, even as modified by Mr. Barnes, were so excessively laborious and complex, that very few attempts were ever made to apply them to ships. The initial stiffness, as determined by the metacentric height, was practically the only element of stability that was investigated. It appears that, prior to 1867, no calculations were made which showed how the stability of a ship became affected by inclining her till the water-line came up over the deck, or at what angle the stability vanished. This was done for the first time at the Admiralty in 1867 by Mr. William John, under the direction of the author of the present work. The results of these investigations were published by Sir E. J. Reed in an interesting and instructive paper upon "The Stability of Monitors under Canvas," read before the Institution of Naval Architects in 1868. Curves are appended to this paper which show how the righting moments vary at successive angles of inclination, and the point at which they vanish. This paper proved conclusively how great are the dangers that have to be guarded against in ships of low freeboard and with high centres of gravity.

The extended application of stability calculations to cases involving greater irregularities in the volumes of the wedges of immersion and emersion than are contemplated by Atwood—such, for instance, as are caused by deck edges becoming immersed, or portions of deck erections becoming included in the volumes of the immersed wedges—created a demand for still more systematic and simple modes of calculation. This was supplied by Messrs. White and John in a paper read before the Institution of Naval Architects in 1871.

Down to the time of the *Daphne* disaster, which occurred in July, 1883, stability calculations made no further progress of importance in this country. At the Admiralty, and in some of our mercantile shipyards, the processes above described were gone through in cases where full knowledge of a ship's stability was considered requisite. Such calculations often took about a month to complete; and the results obtained were usually limited to a knowledge of how a ship's righting moment varied with angle of inclination at one or more chosen draughts of water. Even this was not considered essential when very light draughts of water were being dealt with.

The evidence given at the *Daphne* inquiry, a

report of the Government Commissioner, Sir E. J. Reed, directed attention to imperfections in this department of shipbuilding practice, and furnished a powerful stimulus to renewed inquiry. Valuable results were speedily forthcoming in the shape of more complete and general expositions of the theory of stability than had previously been given: and in a great simplification, which at the same time included an extension, of the system of calculation. One of the most useful portions of the present work is that which describes the improvements thus made in the theory and practice of the subject.

The modern improvement of the theory is shown by Sir E. J. Reed to be in the direction of considering the variation of stability with draught of water, and the amount of stability a ship will possess at light draughts. The *Daphne* inquiry showed that the danger of instability which is sometimes to be found associated with light draught of water was frequently lost sight of because of a prevailing belief that, so long as a vessel has a high side out of water, and any initial stiffness, she will have a large range of stability. This point is clearly and fully dealt with by Sir E. J. Reed in his present work; and he states a general proposition which underlies it, and which was first enunciated by Prof. Elgar in the *Times* of September 1, 1883. It is that, if any homogeneous body which is symmetrical about the three principal axes at its centre of gravity be of such density as to float in equilibrium with its lowest point at a depth x below the water, then if the density be altered so as to make it float with its highest point at a height x above the water, the righting moments will be the same in both cases at equal angles of inclination, and, consequently, the range of stability and complete curves of righting moments will be the same. Sir E. J. Reed also gives copious extracts and diagrams from a paper read by Prof. Elgar before the Royal Society in March last, in which the variation of righting moment with draught of water is shown not only for symmetrical bodies, but also for floating bodies of irregular form and for an actual ship. These investigations indicate that the effect of lightness of draught upon stability may be as prejudicial, or even more so, than that due to low freeboard.

Sir Edward Reed deals very fully with the recent practical developments of the subject, and with the improved systems of calculation that have been devised. These have for their primary object the direct construction of curves showing the variation of righting arm with draught of water at fixed angles of inclination. The wedges of immersion and emersion are no longer dealt with in the stability calculations. Atwood's formula involving the volumes and moments of the wedges of immersion and emersion is discarded, and the following one is employed (see Fig. 1) $GZ = BE - BG \sin \theta$. BE is computed by calculating the under-water volume at the inclined water-line W′L′, and its statical moment. These calculations can be made very quickly and easily with the aid of Amsler's mechanical integrator: and the complication involved by dealing with the two separate wedges, and equating their volumes, may thus be avoided. Sir Edward Reed describes the methods put forward by Mr. W. Denny—who appears to have been the first to suggest this important step—Mr. Macfarlane Gray, Mr. Benjamin, and others.

It is singular that while naval architects in this country were thus working out for themselves those extensions of the difficult problem of stability which modern requirements have demanded with continuously increasing force, the French appear to have been long in possession of a complete and admirable system. So long ago as 1863 M. G. Dargnies was making calculations of stability at Marseilles for numerous angles of inclination, and for four or five draughts of water; and in 1864 M. Reech put forward a most ingenious and perfect method for bringing all the probable stability conditions of a ship into full view and under calculation. The advantages of this method were so striking that it was not long in becoming practically adopted in France, and, in 1870, M. Risbec prepared a paper upon it, together with a calculation form for facilitating its application. Sir Edward Reed gives a concise and clear exposition of the systems of MM. Dargnies, Reech, and Risbec, together with an example of M. Risbec's calculation form. The investigations of MM. Ferranty and Daymard are also described in detail. The latter are probably better known in this country than any of the others referred to, in consequence of a paper which M. Daymard read upon the subject before the Institution of Naval Architects in April last.

There is much in this large and important work to which it is hardly possible to refer, still less attempt an adequate discussion of, within the limits of a short review. We shall return to the subject in a future number. In the meantime, all who are interested in this branch of science, and its bearing upon the construction and safe treatment of ships, will do well to refer to the book itself for full and precise information upon the various aspects of the theory of stability and its practical applications. Fundamental principles are clearly described and illustrated, and may be readily understood by persons possessing an elementary knowledge of mathematics. On the other hand, the elegant and extensive investigations of Dupin, Leclert, Guyou, Moseley, Woolley, and others furnish profitable subjects of study for the most advanced of mathematicians.

OUR BOOK SHELF

Natural History Sketches among the Carnivora, Wild and Domesticated; with Observations on their Habits and Mental Faculties. By Arthur Nicols, F.G.S., &c. (London: L. Upcott Gill, 1885.)

THIS little volume of some 250 pages is full of interest. Treating somewhat of lions and tigers, it has a pleasant portion of a chapter about cats, but the bulk of the volume is devoted to man's faithful friend, the dog. Of the several excellent illustrations we would especially mention the life-like one of a lioness watching its prey, from a drawing by Mr. J. T. Nettleship, which is very full of vigour and muscular force, one of the black-maned African lion, by Mr. C. E. Brittain, and one of Chang, Mr. G. B. Du Maurier's Grand St. Bernard, by Mr. T. W. Wood. As one of the interesting subjects touched on by Mr. Nicols we may allude to that treating of the sense of smell in dogs. He alludes to this in connection with the habit possessed by some dogs of rolling in decaying animal, or even vegetable, substances. On one occasion Mr. Nicols noticed his retriever vigorously anointing himself by rolling about in a clump of living fungi which emitted a particularly evil smell. This is thought to be an inherited habit, or, as Mr. H. Dalziel writes, "Taste and smell being

closely allied senses, this rolling causes pleasurable sensations from association with the glorious feasts enjoyed on battle-fields and on putrid carcases of animals," and from this the author hints that possibly, and even probably, when grouse or venison come to our tables in a state of actual decomposition, this represents a taste acquired years ago by the conditions of a primitive life, and is not to be distinguished from a habit which brings upon our domestic dogs the severest reprobation and prompt chastisement. It seems a subject, however unsavoury, well worthy of being investigated, and doubtless many facts bearing on it in reference to uncivilised people are yet to be narrated. Once we call to mind a small knot of semi-civilised Africans captured in a slave dhow off Mosambique that we interrupted at a midnight feast; they were partly eating and partly smelling a mass of half-putrid fish, which seemed, to say the least, to make them uproarious. They had been under civilisation of a sort since their infant days, but seemed full of hereditary instincts. Mr. Nicols's work is full of his own careful observations, and forms a most pleasant addition to our knowledge of the habits and mental faculties of the Carnivora.

Entwickelung der Ortschaften im Thüringerwald. Von Dr. F. Regel. *Petermann's Mitteilungen*, Ergänzungsheft No. 76. (Gotha: Perthes, 1885.)

THIS is a very complete account of the origin and development of the towns and villages in the region known as "the Thuringian Forest," with a special chapter on the geology, topography, and climatology of the district, and a valuable map. The "Thuringian Forest" extends from Eisenach, on the north-west, to Schleusingen, on the south-east, and covers an area of about 1200 kilometres, with a population of 143,986. The mountains of this region are mainly composed of granite, gneiss, palæozoic strata, and porphyry. About a third of the district is still covered with wood. Formerly there was a great variety of trees, comprising the pine, oak, beech, birch, elder, maple, aspen, and willow; but now the forests consist almost entirely of pines, with a few beech woods between Friederichroda and the mediæval walled town of Schmalkalden. The average temperature is somewhat lower than that of the whole of Germany. In the higher villages neither wheat nor the finer kinds of fruit will thrive, and there is frost during from ten to eleven months in the year. The climate, however, is very healthy, and the beauty of the scenery and purity of the mountain streams attract many visitors during the summer months. The highest, and one of the most popular, of these summer resorts is Oberhof, a village at the top of the pass over the Schützenberg, of which the earliest record is in the year 1267. Only oats and potatoes can be grown here (2541 feet above the sea-level), and even the house-sparrow cannot be acclimatised. Eisenach, the capital of the district, is chiefly known on account of the confinement of Luther in the neighbouring castle of Wartburg, which was erected to guard the Thuringian frontier on the west in the years 1067 to 1070. This fortress was close to the junction of two important roads from Erfurt and Muhlhausen, and, as usual in such cases, a town rapidly grew up at the foot of the hill on which the fortress was built. Eisenach now has 13,000 inhabitants, with three churches and several factories. Other towns and villages not so favourably situated owed their development to the neighbourhood of mines, healing waters, &c. Ruhla, a flourishing town of 4500 inhabitants, was celebrated in the first half of the sixteenth century for its steel manufactures, but foreign competition and heavy taxes nearly ruined the place, and in 1748 the population had considerably diminished. The enterprising spirit of the inhabitants, however, was soon drawn into a new channel by the discovery of mineral waters and the introduction of the manufacture of carved amber and pipe-bowls of imitation meerschaum, an industry which has attained considerable proportions. A somewhat similar history is that of the manufacturing town of Ilmenau, which is first mentioned in the chronicles of the fourteenth century. It flourished as an important centre of the copper-mining district of the Ilm up to the year 1739, when the mines were flooded by an inundation. In 1752 the town was burnt to the ground, and, though partly rebuilt, it shared in the general distress caused by the seven years' war, and did not revive until the beginning of the present century, when the manufacture of glass, porcelain, and toys was introduced. In 1838 the establishment of a hydropathic institution afforded a further stimulus to the trade of Ilmenau, and the population has increased from 1972 in 1809 to 4593 in 1880. On these and other places of less note in the Thuringian Forest Dr. Regel's work affords abundant information, though it is somewhat overcharged with notes and references which serve rather to display the extent of the author's reading than to illustrate his text.

LETTERS TO THE EDITOR

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.*]

River Thames—Abnormal High Tides

REVERTING to my letter of December 19, 1883, inserted in NATURE for January 10, 1884, I append an abstract of salient exceptional tides of last year similar to that accompanying my former letter, from which it will be seen that the maximum elevation of tide is eleven inches less than in 1883, and the excess over the computed rise is also less by seventeen inches than in 1883—in each year resultant on north-north-west gales. Both year's results may be said to be analogous, and each showing how sensitive is the high-water level and how easily it is affected and raised by a change from south and west to northerly winds.

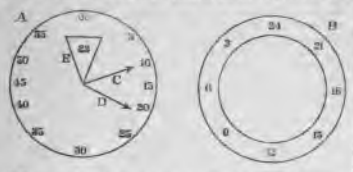
Our Future Clocks and Watches

IT is to be hoped that the absurd dial of which you give a drawing will not come into general use. Why not adopt the convenient shape which for more than a century has been in use

[1] Wind Influence. [2] Northerly Influence.
[3] Still felt. [4] Wind blowing right up the estuary.
[5] Sewage up to Westminster with this tide. [6] N.N.W. day before.
[7] Maximum tide of year; W.N.W. gale day before.
[8] Gale and remarkable fall of barometer = 29° 10′.

on the continent for some jewelled watches?—A is the shape of the visible dial; C is the minute hand; D is the second-hand (sometimes dispensed with); E is an aperture in the dial through which is seen the hour, brought there by the hourly revolution of the wheel B; B is a wheel fixed in watches of the size of a



shilling a series of wheels or a metallic band rolling round a drum of special construction for these tiny watches) immediately under the dial, set in motion once every hour, and bringing the corresponding numbers under the aperture E. CHATEL

Jersey, January 5

THE COAL QUESTION

IT is generally admitted that the amount of coal existing below Great Britain at such depths that it can be worked is limited, that large quantities of coal are annually used, and that even the partial exhaustion of the fields, accompanied, as it must be, by a rise in price, would seriously affect almost all our manufactures, and greatly endanger our commercial supremacy. But if we attempt to go further, and say how long our supply of coal will last, we meet with very different estimates. Nearly a hundred years ago the question was discussed by Mr. John Williams, and though the insufficiency of the data did not allow him to give a definite answer, he at least showed the vital importance of the subject.

In 1861, Mr. Hull, by taking into account the area of all our coal-fields and the thickness of the workable seams, calculated that the total available coal in Great Britain was 79,843,000,000 tons; this result was shown by a second calculation to be slightly too low. Further, he assumed that the output of coal, which was then 86,000,000 tons, could not rise much above 100,000,000, and therefore that our supply was sufficient for eight centuries.

Four years later Prof. Stanley Jevons, in an admirable essay on "The Coal Question," accepted the more important of Mr. Hull's data, but showed that they would bear a very different interpretation, and that, instead of the eight centuries spoken of by Mr. Hull, "rather more than a century of our present progress would exhaust our mines to the depth of 4000 feet." He then shows that the absolute physical exhaustion of the fields is improbable, but that before the twentieth century is far advanced the output of coal will probably be checked by a rise in price so considerable that England will be unable to compete in manufactures with other nations still enjoying the profusion of coal to which her present commercial prosperity is so greatly due. These theories and results were reviewed and strengthened by Prof. Marshall in 1878 ("Coal, its History and Uses"), with the aid of more recent statistics; and the present paper is intended to give a short and simple account of the present state of the question from the physical side, with the omission of the more difficult and dubious arguments which may be drawn from Political Economy.

The arguments of Prof. Stanley Jevons were so conclusive, and his results so alarming, that a Royal Commission, of which the Duke of Argyll was chairman, was appointed, in 1866, to investigate the probable quantity of coal contained in the coal-fields of Great Britain. In 1871 the Commission reported that the coal-fields already in use still contained 90,207,000,000 tons of coal, and t concealed coal-fields as yet unopened, near Doncaster, mingham, and elsewhere, probably contained 56,273,000, tons more, or that, in all, 146,480,000,000 tons of coal w available. Since that time about 1,780,000,000 tons coal have been raised, leaving as the available supply 1884 about 144,700,000,000 tons. Subsequent investi tions show that this estimate is probably considerably high.

These results were intended to include all beds a f and upwards in thickness lying within 4000 feet of surface, though it was rendered probable at the sa time that the amount of coal below 4000 feet is not v large. The reason for excluding all beds less than a f thick is that, at present prices, it is found unprofitable work them, and hence, except in a few special cases, th are left untouched, though rendered worthless for the fut from the disturbance of the strata occasioned by worki the other beds.

Though we may assign no limit below which it is i possible to work, the cost of mining increases so rapi with increased depth that the price of coal must rise v seriously before even the 4000-foot limit can be reache This increase of cost depends upon various causes. T mere sinking of three shafts like those of Murton, wh are said to have cost 300,000*l.*, burdens the undertaki if it last fifty years, with an interest and sinking fund 4 per cent. amounting to 13,965*l.* per annum. More pow ful winding and pumping engines must be employed, a from the great expense of shaft-sinking, larger areas m be worked from one shaft, necessitating extra expense underground haulage, ventilation, and supports. Furth each actual coal-hewer requires a larger amount of assi ance to secure his safety and to remove his winnings m deep pit. A coal-hewer working at an open seam on t surface of the ground would only require one labourer wheel away the coal, while in a deep mine each hew requires about three men to attend to the removal of t coal, the pumping, and ventilation.

The high temperature of the rock at great depths also an important factor in the expense of deep minin In England there is found to be a uniform temperatu of 50° F. about 50 feet below the surface; but this tempe ature is found to increase 1° F. for every 60 feet descende so that at 4000 feet the temperature of the rock will about 116° F. And though this temperature is not suf ciently high to prevent working, and might be lowered few degrees by ventilation, it will cause a considerab increase in the expense, both from the lassitude and ext pay of the men, and the larger amount of air require which even now at Hetton amounts to 450,000 cubic fe per minute.

These difficulties account for the manifest reluctanc to sink deep pits, for the high price charged for the co from them, and for the fact that the 4000-foot limit h not yet been approached. In 1846 the Messrs. Pemberton' pit at Monkwearmouth reached 1720 feet; in 1858 th Astley pit at Dukinfield reached 2100 feet; in 1869 th Rosebridge pit at Wigan reached 2448 feet; in 1884 th Ashton Moss pit near Manchester reached 2688 feet; an though the Lambert pit in Belgium has been worked t 3490 feet, the circumstances were exceptional, and it i certain that the commercial success of such a pit i England would necessitate a price of coal far higher tha it at present is.

The early estimates of the annual output of coal are s unreliable that it is useless to go back further than 185 when "Mineral Statistics" were first carefully collecte by Mr. Robert Hunt, and even in these returns th amounts for the first few years are possibly as much a three per cent. too low, from the difficulties of overcomin the fears of the coal-owners as to the uses which might b made of them. These returns have been collected and arranged by Mr. Meade, in his "Coal and Iron Industries

of the United Kingdom," from which Columns I. and V. of the following table have been for the most part taken.

Since the amounts of coal used are very large, and great accuracy cannot be expected in inquiries of this nature, it is convenient to take as the unit of our calculations 1,000,000 tons of coal instead of our ordinary unit, the ton. This unit may be expressed in several different ways: a cubic yard of anthracite weighs about 2700 lbs., and of bituminous coal from 2090 to 2400 lbs., hence on an average a cubic yard of coal weighs a ton; and our unit of 1,000,000 tons is a cub cal block of coal 100 yards each way, or a bed of coal a mile square and a foot thick. Column I. in the following table gives the annual output of coal since 1854, and the total output during the thirty years, which amounts to 3,245,100,000 tons.

Amount of Coal in Million Tons

Year	I. Won	II. Calculated $64{\cdot}7+3(n-1)$	III. Calculated $62{\cdot}85\times1{\cdot}035^{n-1}$	IV. Calculated $65{\cdot}5\times1{\cdot}0325^{n-1}$	V. Exported

1875	131·9	127·7	129·4	128·2	14·5
1876	133·3	130·7	134·0	132·4	16·3
1877	134·6	133·7	138·6	136·7	15·4
1878	132·6	136·7	143·5	141·1	15·5
1879	134·0	139·7	148·5	145·7	16·4
1880	147·0	142·7	153·7	150·4	18·7
1881	154·2	145·7	159·1	155·3	19·6
1882	156·6	148·7	164·7	160·4	20·9
1883	163·8	151·7	170·4	165·6	22·8
Totals	3245·1	3246	3245·1	3251	351·7

A few comparisons may enable the mind to grasp the real meaning of these enormous figures. It was calculated by Sir Henry Bessemer that the output of coal, 154,000,000 of tons for the single year 1881, would suffice to build 55 Great Pyramids, or to rebuild the Great Wall of China, and to add a quarter to its length! In 1883 the output was 163,800,000 tons, which would form a column a mile square and nearly 164 feet high; or would build a wall from London to Edinburgh 400 miles long, and 45 feet 9 inches high and thick, or another round the world 24,000 miles long, and 5 feet 11 inches high and thick; or, if the Straits of Dover are 21 miles across and 600 feet deep, would make an embankment across them 22 yards wide: while the total output for the 30 years would build a round column 9 feet 4 inches in diameter, which would reach 240,000 miles high, the distance of the moon.

The numbers show considerable fluctuations—as might be expected from the variety of accidental circumstances, such as new inventions, the mean annual temperature, and the state of trade, which affect the amount of coal used—but, on the whole, a very rapid increase; the output for 1875 being double of that for 1854, and that for 1883 double of that for 1862.

If we assume that the increase in annual output would be constant were it not for accidental circumstances, we can represent the actual numbers, with fair accuracy, by an arithmetical series of which the first term is 64·7, and the last 151·7, the increase in annual output being 3, and the total amount 3246 (Column II.). Further it has been shown that the coal still available in 1884 is 144,700,000,000 tons, and we may assume that the output in 1884 will be at least as great as that in 1883, or 163,800,000 tons. Hence, if the output of coal continues to increase at the rate of 3,000,000 tons annually, our supply will last for 261 years, or will be exhausted about A.D. 2145.

But this calculation is open to several objections, and the numbers as shown by Prof. Stanley Jevons may bear a much more serious significance.

It is improbable that the annual difference should always remain the same, and in fact, in the calculated series (Column II.), while all the early terms are higher than the real outputs, the later terms are lower, showing that the difference itself probably increases. If we calculate the series backwards we have no output at all about 21 years before 1854, a result we cannot agree with, and for all years before 1833 a negative output, a result we cannot understand. Hence it is probable that the results may be better expressed by another kind of series.

Theory and experience show that the same causes always produce the same effects, unless fresh circumstances intervene to modify the effects produced. Thus the population of England, which was about 9,000,000 in 1801, became 18,000,000 in 1851, or doubled in 50 years; hence, if no new causes intervene, we should expect it to double again in the next 50 years, or to become 36,000,000 in 1901. This is usually expressed by saying that social statistics in general show uniform multiplication in uniform periods, or obey the compound-interest law, or form a geometrical series. As an example of this law let us examine a little more closely the population of England and Wales. The increase for each 10 years since 1801 is itself perpetually increasing, or the numbers must be expressed by a geometrical series of which the ratio is nearly 1·147, and not by an arithmetical series.

Year	1,000,000 Inhabitants	Increase in Ten Years	Calculated $8{\cdot}89\times1{\cdot}147^{(n-1)}$
1801	8·89		8·89
1811	10·16	1·27	10·20
1821	12·00	1·84	11·70
1831	13·90	1·90	13·42
1841	15·91	2·01	15·39
1851	17·93	2·02	17·65
1861	20·07	2·14	20·24
1871	22·71	2·64	23·22
1881	25·97	3·26	26·63
Sum...	147·54		147·34

From the dependence of the numbers representing the annual output of coal upon the number of inhabitants, it might be expected that they also can be expressed by a geometrical series, and this has been shown by Prof. Stanley Jevons to be the case. According to his calculations the ratio of the series is about 1·035, or the rate of increase of the output is about 3½ per cent per annum, and it may be assumed for the reason before given that the sum of all the outputs is likely to be more approximately correct than the single output for 1854. The annual outputs calculated from these data are given in Column III., and show a fair approximation to the actual numbers, though the first term is rather low, and the last six terms are nearly as much above the true results as those in

wasteful, open fireplace into the dull, though economical Continental stove.

The trade in coal and coke, especially to France, Germany, Russia, and Sweden, has reached very considerable dimensions, and is, in fact, the fourth most important of our exports. In Column V. it will be noticed that the 3,400,000 tons exported in 1854 have become in 1883 22,800,000 tons, worth more than 8,000,000*l.*, or in thirty years the export of coal has multiplied more than six times. Any considerable lessening in this amount would of course seriously affect the balance of our trade with other countries.

It seems hardly necessary to meet the objection that when our own stores are exhausted we may import coal from other countries. A few considerations will show the fallacy of such reasoning. The nearest stock of coal on which we can hope to draw is that in Canada and the United States. The former supply is plentiful, but much of it is badly situated for exportation. In the United States coal is found in Virginia, Utah, and the Western States, and the basin of the Mississippi and its tributaries contains coal-fields estimated to cover 200,000 square miles, and to contain about 38 times as much available coal as Great Britain. According to Mr. Hull, these fields could as easily supply an output of 2,704,000,000 tons as we can one of 90,000,000.

Putting aside the commercial difficulties dwelt on by Prof. Stanley Jevons in the way of converting a large export trade in our staple raw material into an immensely larger import trade, the fact that even now the rivalry with the ingenuity and perseverance of the American manufacturers, aided though we are by their high tariff, demands all our skill and energy, and the almost universal law that manufactures cluster round the source of power, the physical difficulties of such a traffic would be enormous. Suppose a steamer similar to the *Faraday* capable of carrying 6000 tons, and so swift as to be capable of making 13 trips from America in the year; she would annually bring 78,000 tons of coal, or it would require a fleet of 2100 such ships to supply even our present requirements. And if the coal could be supplied to our shipping in American ports at 10*s.* a ton, we should have annually to pay America 81,900,000*l.*, an amount not far below our present national income. The further cost of carriage across the Atlantic and delivery in English towns, must raise the price of coal to many times what we at present pay.

We are brought, then, face to face with the last of the four above-mentioned possibilities. Before very many years are past we must expect that the scarcity of coal in England will cause a considerable rise in price, which will directly affect all such branches of trade and manufactures as depend upon coal, and indirectly all other branches.

What this means in the former case will be evident from a brief consideration of the uses to which coal is applied, a few instances of which have already been given. Let us take one instance of the latter class—the importation of food-stuffs. The increase in the population of England per square mile, which was 37 in 1066, 75 in 1528, 140 in 1780, 241 in 1831, and 443 in 1881, higher than any civilised country except Belgium, has taken place far more in manufacturing than in agricultural districts, and has necessitated a great change in our supply of food. Previous to 1780, though luxuries were imported, the staple food-stuffs, corn, meat, cheese, &c., were produced at home; now, on the other hand, we import more than one-third of our meat, half of our cheese, and nearly two-thirds of our wheat. Owing to our luxuriousness and to this large importation of food, averaging 212 lbs. annually per head, the average annual cost of food per head in England, 13*l.* 9*s.*, is higher than that in any other country. When by the scarcity of our coal our pre-eminence in cheapness of manufactures becomes a thing of the past, the means of paying for this food will gradually cease, and the pressure of population, together with the increased cost of the necessaries of life, by emigration, by an increased death-rate, and by a reduced birth-rate, will change the England of to-day into a country like the England of 1780, —a country with a comparatively scanty population, with few manufactures, supporting themselves by the produce of their fields, and looking back on the England of to-day as the Spaniard now looks back on the Spain of Philip II. —of Philip, the husband of Mary of England, the ruler of Spain, Portugal, the Netherlands, the Milanese, of Malabar, Coromandel, and Malacca—of Philip, whose father had sent Cortez to conquer Mexico, and Pizarro to Peru, and who himself, by the conquest of Portugal, had annexed the valuable province of Brazil. Looking at such a picture, is it impossible that the England which now rules over 8,600,000 square miles, containing 283,000,000 inhabitants, should shrink to its former limits of 122,000 square miles, with 8,000,000 inhabitants?

Finally, let us consider if anything can be done to defer or mitigate this change in the condition of our descendants. After discussing and rejecting the expediency of limiting or taxing our output or export of coal, on the ground that any such measure would impose a serious burden upon our manufactures and commerce, and in fact produce the very result we are trying to avoid, Prof. Stanley Jevons proposed that instead of relieving ourselves by the remission of taxation, we should relieve our descendants by making a serious effort to pay off the National Debt. The amount of the debt, which was 900,000,000*l.* in 1815, was 839,918,443*l.* in 1857, and 756,376,519*l.* in 1883. Thus in 68 years about 144,000,000*l.* have been paid off. He proposed that the probate, legacy, and succession duties, as being in reality capital and not income, should be applied to this purpose. These duties amounted in 1883 to about 5,600,000*l.*, and would suffice to pay off the National Debt in about 55 years. These proposals have been in part carried out. The amount of taxes remitted has of late years been considerably reduced, and in 1883 terminable annuities were created, which in 20 years will reduce the debt by 173,000,000*l.*

On the other hand, the rapid increase in local obligations to some extent renders nugatory this attempt at national economy. It is somewhat difficult to obtain accurate data on these points, but the bonds of the Metropolitan Board of Works, of Liverpool, of Manchester, and of Leeds, quoted on the Stock Exchange, represent a sum of 34,000,000*l.*, and no doubt other towns are following far too rapidly in the same direction. Of course some of this expenditure represents profitable enterprises, such as the supply of gas and water, but it is to be feared that a considerable amount has been spent in ways less directly or indirectly remunerative.

If, then, we are unable to arrest the action of those physical and commercial laws which will press with more and more severity on our descendants, let us do what we can to mitigate their fate by using every exertion to avoid unnecessary increase in our obligations, and to reduce those transmitted by our fathers. It would probably be well also to appoint a fresh Royal Commission to investigate more accurately than has yet been done the various data upon which these calculations depend, to make more widely known any improvements made during the last thirteen years which may prolong the duration of our coal, and to consider the most important financial questions which are involved in this inquiry.

And at last, when the worst comes to the worst, we may take comfort from the thought that, beyond the four seas, new Englands, as yet hardly conscious of their capacities, stretch east and west, and that the New Zealander, who a few years hence may moralise on the last stone of London Bridge, will mingle reverence with his philosophy. will be no dark-skinned, far-off cousin, but a ruddy, grandchild.

SYDNEY LU

INVIGORATION OF POTATOES BY CROSS-BREEDING

SOME interesting experiments on the potato were tried at Reading last summer. Most persons are aware that changes which are called "improvements" from a commercial point of view have been effected among the plants of the farm and garden in recent years by "hybridising," and that the usual result of hybridising plants is to invigorate them. Mr. Darwin explains the law which horticulturists avail themselves of in the improvement of plants when he says, "All forces throughout Nature tend towards an equilibrium, and for the life of each organism it is necessary that this tendency should be checked." ("Animals and Plants under Domestication," vol. ii. p. 130). He adds, hence "the good effects of crossing the breed, for the germ will be thus slightly modified or acted on by new forces." The invigoration consequent on changing seed corn from one district to another is due to the same causes, as well as the "evil effects of close interbreeding prolonged during many generations, during which the germ will be acted on by a male having almost identically the same constitution."

It would not be easy to ascertain the history of cross-breeding in gardens. Hybridisation has been called "a game of chance played between man and plants." All the great breeders of florists' flowers, and of fruits and vegetables, have practised the art successfully, but as regards the potato recent investigations have shown that the law of "changed conditions" has not been obeyed. The term "hybridising," as used by horticulturists, is a relative expression, referring sometimes to the crossing of widely distinct forms, and in other cases to the injurious union of closely connected forms. Hitherto the breeding of potatoes has involved this vicious principle of too close interbreeding, no other plant of the farm having been more constantly intercrossed.

Some years since the cross-breeding of English and American potatoes was extensively practised, and to some extent, undoubtedly, the "conditions of life" of the varieties which were brought together from either side of the Atlantic were changed; but the cultivated potatoes both of England and America belong to the same species, and having both alike become enfeebled and subject to the same disease, the experiment of interbreeding failed in its object.

Under these circumstances a veteran breeder wrote, "I have come to the end of my tether!" and he gave up the breeding of potatoes in despair. This year he has recommenced it, working hopefully with the aid of a new species, and owing this new departure to the suggestion of the eminent botanist Mr. J. G. Baker, F.R.S., of Kew.

Mr. Baker undertook a scientific examination of the various tuber-bearing species of Solanum, for the purpose of ascertaining whether *S. tuberosum*, the cultivated potato, might not possibly be invigorated by hybridising it with some other species of the family. Writing in the *Journal* of the Linnean Society, Mr. Baker says:—

"The subjects of the differential characters, the relationship to one another, and the climatic and geographical individuality of the numerous types of tuber-bearing Solanums are of great interest both from a botanical and economic point of view. As there are many points which are still to be unravelled, I propose in the present paper to pass in review the material which we possess in England bearing on the question. It was at the instigation of Earl Cathcart that I undertook the inquiry; and in carrying it out I have gone through all the dried specimens at Kew, the British Museum, and the Lindley Herbarium, have carefully studied the wild types which we grow in the herbaceous ground at Kew, and have visited the extensive trial-grounds of Messrs. Sutton and Sons at Reading, whose collection of cultivated types in a living state is probably the most complete in existence."

Bearing in mind that the potato, the most produc of our food-plants, has become the most uncertain am them in regard to its annual produce, it is not surpri that it should have been the subject of voluminous wri and continual inquiry. But, in spite of all the pa which have been expended on this stricken esculent, one but Mr. Baker seems to have recognised the outr of in-and-in breeding to which it has been subjected. seems doubtful whether the numerous breeders w aware that the cultivated potato had been made the s ject of continual in-and-in breeding, since it had ne been crossed out of its own family during the 250 ye of its highly artificial treatment in this country as a c tivated plant. Yet this has been the case, as Mr. Ba shows in his enumeration of the six tuber-bearing spe of the plant. As the habitat as well as the distinctiv of species of Solanum affect the subject, the follow brief details have been taken from Mr. Baker's paper

"(1) *S. tuberosum*.—Andes of Chili, Peru, Boliv Ecuador, and Columbia; also in the mountains of Co Rica, Mexico, and the South-Western United States.

"(2) *S. Maglia*.—Shore of Chili, down south as far the Chonos Archipelago; also likely Peru.

"(3) *S. Commersoni*.—Uruguay, Buenos Ayres, a Argentine Territory, in rocky and arid situations at a l level.

"(4) *S. cardiophyllum*.—Mountains of Central Mexi at an elevation of 8000 to 9000 feet.

"(5) *S. Jamesii*.—Mountains of South-Western Uni States and Mexico.

"(6) *S. oxycarpum*.—Mountains of Central Mexico."

According to Bentham and Hooker, the great genus Solanum—the largest in the world—consists of decided distinct species, and if we omit some of the so-call species which are really only varieties of *S. tuberosu* these six species alone bear tubers.

In attempting improvement by crossing the cultiva potato, it is useless to continue the system of interbree ing with its own varieties; and, on the other hand, t lesser forms of wild potatoes, such as *S. Jamesii*, a pla of eight or ten inches in height, must be rejected. M Baker recommends two species as best for the breede purpose, *S. Maglia* and *S. Commersoni*. Both these ka yield good crops of fair quality under cultivation, and th possess the advantage of coming from a moist clima This is a point of great importance. When Mr. Darwi a young naturalist in 1835, was writing his account "The Voyage of the *Beagle*," he mentioned having se the potato growing wild on the shores of the islands of t Chonos Archipelago, in South America, and he thoug it surprising that the same plant should be found in t damp forests of those islands and on the sterile mountai of Central Chili, where a drop of rain does not fall f more than six months. The explanation of this anomalo circumstance is that the potato of the islands and lo lands belongs to a different species from that of th mountains, the latter being identical with the cultivate potato of Europe and America, while the former is *S Maglia*, which is at any rate hardy, vigorous, and health and in all respects apparently well suited for crossing wi the cultivated sorts. This is the potato which Mr. Bake recommends. Earl Cathcart had asked him for any sug gestions that a botanist might be able to offer to breeder founded upon scientific knowledge of the potato general and of the geographical distribution of the family.

On this part of his inquiry, Mr. Baker observe that potato-growers work upon the assumption th the one purpose of the plant's existence is the productio of potatoes, which is in fact only an incident in its lif *S. Maglia* has been grown at Kew among the herbaceou plants since 1862, and in that dry sandy soil, witho manure, it produces few if any tubers, or only of sma size. On the other hand, two tubers were sent to Chi wick and grown there in the gardens of the Royal Hort

"[illegible] tion [illegible] indis- [illegible] Sola- [illegible] econ- [illegible] are [illegible]

test, by gradual stages to *Ascidia mammillata* (Fig. 5), where the vessels are numerous all over the test, branch freely in its outer layer, and terminate close to the surface in large ovate bulbs, which are usually found filled with blood-corpuscles.

The only part of this history which presents any difficulty is the passage from the Clavelinid to the Cionid arrangement, from the gemmiparous stolon to the first traces of a respiratory system of vessels. This can, I believe, be most satisfactorily explained by assuming that the rudimentary stolons after they had lost their primary function became useful as adhering organs (Figs. 2 and 3), and consequently were retained or possibly increased by the action of natural selection, until their respiratory function became established.

I hope to work out the modifications of the system throughout the various groups of Ascidians in detail, and the results will probably be given in Part II. of the Report on the *Challenger* Tunicata.

W. A. HERDMAN

NOTES

THE Council of the Royal Astronomical Society have awarded their gold medal to Dr. W. Huggins for his researches on the motions of stars in the line of sight and on the photographic spectra of stars and comets. The presentation takes place at the annual meeting next month. This is the second time that Dr. Huggins has received the medal, he having, in 1867, in conjunction with the late Prof. Miller, received it for his researches in astronomical physics.

THE will of Mr. George Bentham, who died in September last, has been proved by Sir Joseph Dalton Hooker and the Right Hon. Sir Nathaniel Lindley, the executors, the value of the personal estate amounting to over 23,000*l*. The testator bequeaths, among other sums, 1000*l*. each to the Linnean Society of London and the Royal Society Scientific Relief Fund. The residue of his real and personal estate is to be held upon trust to apply the same in preparing and publishing botanical works, or in the purchase of books or specimens for the botanical establishment at Kew; or in such other manner as the trustees may consider best for the promotion of botanical science.

AT the meeting of the Colonial Institute on Tuesday, Gen. Sir Henry Lefroy read a paper on the meeting of the British Association in Canada. Sir Lyon Playfair, M.P., referred to the visit of the British Association as marking a point in the advance of civilisation. Canada's position of having federated, not under the pressure of war, but in a time of profound peace, was unique in the history of the world. The science of Great Britain belonged to the Empire, and it was right that Canada should be the first to try to federate the science of the United Kingdom, and distribute it over the Empire. What Canada wanted was not pure science, but applied science, to bind together her vast territory by railways. But knowing that applied science did not come except pure science preceded it, Canada had had the forethought and wisdom to welcome that pure science to the Dominion. Sir Lyon gave a humorous account of an adventure he had in a wild part of Ottawa with a Scotch mining manager. It turned out that the manager, when in Scotland, had attended the Mechanics' Institute at Glasgow, and afterwards the evening classes at the Andersonian Institution, obtaining a knowledge of chemistry and mineralogy, which had stood him in good stead on emigrating to Canada. From his compatriot he (Sir Lyon) heard of many other Scots of a like type, all of whom had got on well, from the scientific education they had acquired at similar institutions. For such men he did not know any better country than Canada to find openings for getting on in the world. Prof. G. T. Bonney spoke at some length of the interesting geological formation of Canada, and said he believed that the district north of the St. Lawrence was rich in valuable minerals, and that exploring parties for their discovery should be organised to supplement the systematic geological survey which was being slowly conducted. He condemned the wasteful treatment of the forests that was going on in some of the parts he had visited, and suggested that it was a matter which should engage the attention of the Dominion Government.

ON Tuesday evening Sir Frederick Bramwell gave an address at the Institution of Civil Engineers on his assuming the chair for the first time since his election as president. Sir Frederick's subject was suggested to him by the forthcoming Exhibition of Inventions, his address consisting mainly of a review of some of the most remarkable recent inventions in the application of science to engineering. Sir Frederick has apparently given up hope of our being able to put the tides to any practical use, and hints that Khartoum might have been relieved long ago had our aëronauts been as inventive, or our War Department as enterprising, as those of France.

M. COCHERY, the French Minister of Posts and Telegraphs, was present, on January 2, at Rouen to witness some interesting experiments in telephoning to a great distance. The object was to test the results of the application between Rouen and Havre, a distance of 90 kilometres, of M. Van Rysselberghe's system of instantaneous transmission. The experiment was perfectly successful, and during more than one hour, messages were exchanged between Rouen and Havre. The Minister announced, on leaving Rouen, that the communication would be open to the public in about a fortnight. Since January 1 the first telephonic offices have been open in Paris, and it is probable that communication will soon be established between Paris and Rouen.

MR. LANT CARPENTER lectures on Sunday at the Sunday Lecture Society, on "The Life and Work of Sir William Siemens," illustrated by experiments, diagrams, and the oxy-hydrogen lanterns. Mr. Carpenter has, we understand, obtained some special materials, of which he will make use in his lecture.

REPORTS from Brussels state that the Spanish earthquake, or a similar simultaneous earthquake, was felt at the Royal Observatory there. The Observatory is stated not to be provided with special instruments for recording earthquakes, as these phenomena are so rare and slight in Belgium. It is said that on December 26 last, the day succeeding the first great shock of the Spanish earthquake, one of the astronomical clocks in the principal meteorological station in the Boulevard de l'Observatoire was stopped, and the other went irregularly. The officer charged with attending to them perceived that the pillars on which they rested had been displaced, and were no longer vertical. On the evening of the same day, M. Lagrange, when about to make some observations, noticed that the large telescope was also displaced. It appears from this that the undulations of the crust of the earth, which have had such disastrous effects in Spain, extended as far as Brussels, and although their effects were not generally appreciable in the latter city, yet they were noticeable in the case of delicate instruments, such as astronomical clocks. It would be interesting to have a precise, authentic statement on this subject, and also to learn whether similar effects were noticed anywhere else in Europe during the last week of the old year.

AT a recent meeting of the German Asiatic Society of Japan a paper was read by Dr. H. Muraoka of Tokio, on the magic mirror of Japan. It is generally supposed that its magical quality was discovered only recently; but it was, says Muraoka, known for a long time in Japan. Old ladies

told him that in their youth, fifty years since, they frequently noticed, when at toilet, that the reflection of the sun from the mirror on the wall or ceiling contained the figures or letters on its back. It is said to have been known to the Romans in connection with some of their mirrors, and any one concealing a mirror possessing this quality was arrested as a sorcerer; but the authority for this statement is not given. The subject is engaging considerable attention, as will be seen from the fact that in recent years a list of fourteen writers on the subject is quoted, from Stanislas Julien, in 1847, to Messrs. Ayrton and Perry quite lately; and, as the subsequent discussion showed, there are omissions even in this list. These writers, especially the two latter, have demonstrated beyond doubt that unequal convexities in the mirror beget its magical quality. The polished surfaces are convex, but the convexity is not continuous, and is broken in certain places. After going over what had already been done on the subject, and its results, the author described his own investigations. The riddles of the mirror are far from being all answered by the discovery of unequal convexity. For example, how is the inequality caused—by pressure, heat, or by changes in the molecular tension of the metal plates? The writer tried many experiments to answer the question, and he succeeded by means of chemical agents in drawing lines on the flat back of a mirror, which were reproduced on a reflected image from the front. His results are: That the irregularity in the convexity is caused by the grinding, which alters the molecular tension, that the magic mirror may be produced at will (it was generally supposed to be the work of chance alone), and that the magical quality attributed to it is not confined to Japanese bronze, but is common to all firm, elastic substances. A curious process employed by mirror-workers is described by Dr. Muraoka: it appears to be one of the secrets of the craft. If the surface of a mirror has been made concave by mechanical pressure, the injury is not repaired, as might be expected, by hammering the other side, or otherwise forcing the metal back into its place. The workman takes an iron tool with rounded, but slightly rough, top, and rubs the concave portion of the mirror in all directions, until a fine network of scratches has been formed. The place then rises of itself, and, instead of being concave, becomes more convex than the rest of the surface. This convexity is then shaved away with a knife made for the purpose, until it becomes even with the rest of the mirror. When this is done the whole surface is again ground, polished, and amalgamated.

A STRANGE Japanese custom has, according to the *Japan Mail*, been brought to light by the working of the conscription law. The head of a certain family was instructed that the time had come for his son, whose name was on the census list, to undergo medical examination prior to actual enlistment. The father lost no time in informing the authorities that the individual referred to, though bearing a male name, was his daughter. He explained that having lost two daughters, both about one year old, he had been driven to this expedient to keep the third alive. It appears, further, that in many districts of Japan people still resort, in their anxiety to prolong the lives of their children, to the custom of bestowing upon their offsprings names ordinarily given to infants of the opposite sex, whenever death has made frequent visits to their households. The present case occurred in the capital.

AN important memoir by Lieut. Casey on the North American species of beetles of the sub-family *Stenini* has just been published. It extends to over 200 octavo pages, and describes in minute detail nearly 170 species, of which the greater part are new, and should form one of the most important contributions to systematic entomology in the States that have appeared. "*Stenus*," in the broad sense, is well defined as a whole, but is notoriously difficult in detail. When genera become unwieldy owing to the mass of species included, it is a convenience to students if they can be split up by recognisable divisional characters. Acting on this idea, Casey has split "*Stenus*" into *Stenus* and *Areus*, on tarsal structure. This subdivision equally affects European (and even British) species.

MR. ALDERMAN W. H. BAILEY, as President of the Manchester Society of Engineers, gave an interesting inaugural address on the 10th inst., his subject being "The Reign of Law in Relation to the Unification of Engineering Work." "The reign of law," Mr. Bailey stated, "is imperial in the domain of the engineer. He deals with forces which have definite, fixed values. If he perceives a quantity or a force he knows that he can identify the same measure or quantity of the like whenever he meets with its equivalents under equal conditions. We know that chance does not rule, and if there be conditions that are indefinite or obscure to us it is not because there is no law, but because we are ignorant of its records." This text Mr. Bailey illustrated by reference to the necessity of exact measurement, supporting his position by numerous examples.

PROF. F. ELGAR is about to deliver a special course of evening lectures, in the University of Glasgow, upon "The Buoyancy and Stability of Ships." The course will consist of twelve lectures, commencing on the 22nd inst. These lectures are intended not only for students of this branch of the science of naval architecture, but also for the convenience of draughtsmen and others who are employed in shipyards during the day, and who are unable to attend the regular University classes.

IN the report of the Meteorological Service of Canada for 1884, attention is again called to the advisability of establishing a marine department in connection with the Meteorological Service for the purpose of organising a system of observations on the ocean by steamers crossing the Atlantic and by those trading with ports in Brazil and the West Indies. Canada, having great shipping interests, should, it is thought, take her part in the great international work now going on of charting the meteorological conditions prevalent over the Atlantic, and in the general development of ocean meteorology. Such observations in the North Atlantic would, it is stated, be of great value, especially in perfecting knowledge of the movements of a particular class of storms. Recent investigations on the subject of the climatic relations of Canada to European countries show that the Dominion has the latitudes of Italy, France, Germany, Austria, the British Islands, Russia, Sweden, and Norway, and has as many varieties of climate as have those countries. There is greater cold in winter in many of the latitudes of Canada than in corresponding latitudes in Europe, but the summers are about the same. The most southern part of Canada is on the same parallel as Rome, Corsica, and the northern part of Spain; it is farther south than France, Lombardy, Venice, or Genoa. The northern shores of Lake Huron are in the latitude of Central France, and vast territories not yet surveyed lie south of the parallel of the northern shores of Lake Huron, where the climate is favourable for all the great staples of the temperate zone.

WITH the new year *Cosmos*, the well-known French scientific journal, will enter on a new period. The size will be increased, in order that larger illustrations may be introduced. It will in future consist of 64 columns, two on a page, each of which will contain more matter than its present page.

THE additions to the Zoological Society's Gardens during the past week include a Pig-tailed Monkey (*Macacus nemestrinus* ♂) from Java, a Macaque Monkey (*Macacus cynomolgus* ♀) from India, a Vulpine Phalanger (*Phalangista vulpina* ♀) from Australia, presented by Mr. J. Church Dixon; a Mouflon (*Ovis musimon* ♂) from Corsica, presented by H.R.H. the Duke of Edinburgh, K.G.; a Vulpine Phalanger (*Phalangista vulpina*)

from Australia, presented by Mr. B. C. Parr; a Short-toed Eagle (*Circaetus gallicus*) from Suez, presented by Capt. H. E. Robbins; a Lacertine Snake (*Cœlopeltis lacertina*) from North Africa, presented by Mr. R. F. Sibbald; a Rose-crested Cockatoo (*Cacatua moluccensis*) from Moluccas, deposited; a Black and Yellow Hawfinch (*Mycerobus melanoxanthus*) from Yarkland, a —— Pastor (*Sturnia* ——) from the Andaman Islands, four Starred Tortoises (*Testudo stellata*) from India, a Tuberculated Iguana (*Iguana tuberculata*) from South America, purchased.

OUR ASTRONOMICAL COLUMN

THE NAVAL OBSERVATORY, WASHINGTON.—The Report of the Superintendent of this establishment, Commodore S. R. Franklin, to the Navy Department, for the year ending October 31, 1884, has been issued. Great stress is laid upon the importance of commencing the buildings for the new Observatory. The present site is stated to be notoriously unhealthy, and the buildings are in a dilapidated state, and, as the ground for the new Observatory has been purchased and the plans made and approved, the Superintendent urges that Congress should be appealed to during the coming session for a portion at least of the funds required for the new Observatory. His estimate "For the purpose of erecting a new Naval Observatory and necessary buildings upon the site purchased under the Act of Congress, approved February 4, 1880," amounts to 586,138 dollars, or approximately 120,000*l*. The 26-inch equatorial was chiefly employed in observations of the satellites of Neptune, Uranus, Saturn, and Mars; in the case of Uranus, the observations were confined mostly to the two outer satellites, and have now been discontinued, as the favourable time for determining the position of their orbits has passed. Since this instrument was mounted in 1873 observations of the faint satellites of the planets have constituted its main work, and the laborious discussion of the observations, with the view to the correction of orbital elements, was commenced in earnest in August 1883, and is now in a very advanced state, particularly as regards the satellites of Saturn. A report from Prof. Harkness, in charge of the work for the Transit of Venus Commission, is appended: the measurements of the negatives obtained at the various stations was completed last August; the number of photographic plates giving satisfactory results is 932 for the northern and 639 for the southern hemisphere. Prof. Harkness enters into details with respect to these measures, and the method of conducting them, for which reference must be made to the report. The Superintendent regrets that the printing of the Washington observations is not so advanced as is desirable, and proposes applying to Congress for a sum of 1000*l*. annually for a few years, in order to bring up work to date, after which a smaller sum would allow of the due publication of the observations.

THE DEARBORN OBSERVATORY, CHICAGO.—The report of the Director of this Observatory, Prof. G. W. Hough, dated June 18, 1884, has been received within the past week. The work with the 18-inch equatorial was confined, as usual, during the previous year to the observations of a few special objects, including Pons's comet of 1812 on its reappearance, difficult double-stars, the planet Jupiter, and the satellites of Uranus. Thirty-two new double-stars, most of which are difficult, were detected. The companion of Sirius was measured by Prof. Hough on eleven nights, and by Mr. Burnham on ten nights, the mean result being

1884·185 ... Position, 36°·6; Distance, 8″·45.

which, with the observations of recent years, seems to indicate that the period of revolution of the companion is longer than that indicated by theory. The disk of Jupiter was observed on every favourable occasion, and micrometric measures made on the principal spots and markings, including the great red spot first remarked in 1878. With best vision the colour of this object in 1883-84 was "unmistakably a pale pink." The spot is stated to have maintained its size, shape, and outline during the five years it has been observed at Chicago; in this respect experience there has not fully accorded with the impressions of some observers, that the spot had "lost its outline, and become merged in a faint belt on the following end." The most marked change has been in its degree of visibility, but it was seen at Chicago as long as the planet was observable. Prof. Hough adds that from 1879 to 1883 the spot had a retrograde drift in longitude upon the surface, or, in other words, the apparent rotation of Jupiter was increased from 9h. 55m. 34·0s. in 1879 to 9h. 55m. 38·4s. in 1883. During the last opposition this drift appears to have nearly ceased. The mean period from September 12, 1883, to June 11, 1884, comprising 660 rotations, is 9h. 55m. 38·5s., and the mean for the whole five years of observation is 9h. 55m. 37·0s. The report is accompanied by six tinted lithographs of the appearance of Jupiter's disk. Saturn was frequently examined with the view to detecting markings on the rings, but all observations so far in this direction have been negative. While the rings have been sharply defined, and even the boundary of the dark ring well seen, "nothing indicating a division in the outer ring has ever been noticed." This is not in accord with the conclusion of many other observers provided with telescopes of less optical capacity than the Dearborn refractor.

GEOGRAPHICAL NOTES

A SO-CALLED "envoy" of the Mayor of Timbuktu, lately arrived in Paris, has been received by the French President, and introduced to the Geographical Society at its last meeting. On this occasion it was stated that there is no Sultan or military authority in this famous metropolis of Negroland, but only a body of merchants who yearly elect a kind of mayor from amongst themselves. This statement is not quite correct, and, as little is known regarding the internal affairs of the city, the following facts will be acceptable:—For over 200 years Timbuktu has been administered by a "Kahia," a kind of burgomaster, originally appointed by the Emperor of Marocco from the Moorish Andalusian family of Er-Rami some time after the expulsion of the Arabs from Spain. The office became hereditary in this family, and the present Kahia, or "Amir," as he now affects to call himself, is Muhammed Er-Rami, whose Negroid features are the result of long alliances with the surrounding Souhray population. He commands little influence, and is practically a mere puppet in the hands of whichever of the rival Arab, Imosharh (Berber) or Fulani (Fulah), factions happens for the time being to have the upper hand. The Imosharhs command the whole district between Timbuktu and Arawán, and their Sheikh or "Sultan," Eg-Tandagumu, seems to draw his chief supplies from the plundered caravans passing through his territory. The Arabs, as in the time of Barth, are still ruled by the head of the illustrious El-Bekay family, a branch of the Kuntza tribe, whose present chief is Sheikh Abadin. His policy has long been to side with the Fulani, whose power here, as elsewhere in the Western Sudán, is constantly on the increase, and who threaten to become absolute masters of Timbuktu unless this place falls into the hands of some European power advancing from the west or penetrating up the Niger valley from the south.

ACCORDING to the *Turkestan Gazette*, Dr. Grishimailo, the traveller and entomologist, has concluded his investigations into the natural history of Turkestan for the present. He began his travels in the Fergana Valley, and from thence he went into the Altai region, which he examined thoroughly. In the course of the summer he visited Osch, Arawan, Nankat, Utch-Kurgan, Shahimardan, Karakazyk, Koksu, Tekelik, the River Balykty, Karamuk, and Zanku; on his return he visited Karamuk, Jirgetal, Sarzbulak, Koksu, Altyumazar, and went on foot through the Trans-Altai Mountains to Bordooba and Karakul. The geological collections are very considerable. In lepidoptera alone there are 17,000 specimens, amongst them being many new kinds. The expedition was also a success from an ethnographical and anthropological point of view. Many heights were measured and thermometrical observations made throughout the whole journey. The traveller met many evidences of the existence of a glacial epoch in Central Asia: amongst these are mentioned the presence of forms in Thian-shan, which hitherto have only been found in Labrador, Greenland, Lapland, and the Swiss Alps. Next year Dr. Grishimailo contemplates visiting the western offshoots of the Thian-shan range, because this locality has never yet been examined thoroughly from a geological point of view.

AT the last meeting of the Geographical Society of St. Petersburg, M. Beliaffsky made a communication respecting journey which he undertook in order to explore the central i

[illegible] of refuse, which has an average depth of [illegible] feet, and which contains the shells of *Mytilus edule*-

genicus, of *Aulacomya magellanica*, of *Patella magellanica*, fragments of *Otaria jubata*, and a few other mammals, but no human remains, no traces of pottery, no bones split for the extraction of the marrow, no arms or manufactured objects beyond a few rude spear- or arrow-heads. All this offers the most striking analogy to the more recent and modern refuse heaps now being formed, and seems to point at a continuity of population since early quaternary times. The absence of human remains or split bones might even imply that the primitive inhabitants, like their present descendants, were at no period addicted to anthropophagy. In other respects the latter occupy an extremely low social position. They practise no arts beyond the manufacture of frail bark canoes, unchanged since the time of Drake's visit, shell knives, bows, darts, and harpoons. The wigwams are branches stuck in the ground and gathered to a point above, or else a mere guanaco skin (among the Onas) suspended from a tree to windward. Their food is mainly fish, crustaceans, wild berries, mushrooms, cetaceans, greedily devoured in a highly putrescent state. They believe in ghosts and demons, but have no idea of a god, or of any religious worship; are guided rather by instincts than by reason; lack even the maternal sentiment, at least after the period of weaning; show no feeling of real affection for friends or kindred, the only developed sentiment being that of pure selfishness. Their stupidity is such that they are unable to count beyond three, after which everything is *varw*—much, many. Yet, in the face of all this the writer was assured by the English missionaries now evangelising these primitive or debased peoples, that the language of the Yahgans, into which they have translated the Gospel of St. Luke, contains no less than 30,000 words, "a wealth contrasting strangely with their present low state of culture, and naturally suggesting the hypothesis of an origin very different and far superior to the present." But, assuming a former higher state, the difficulty is to understand how such a rich linguistic inheritance could have been preserved for countless generations in their present degraded condition, and amid the adverse surroundings of their present habitat. On this subject clearly more light is demanded.

CHARACTERISTICS OF THE NORTH AMERICAN FLORA[1]

II.

THIS contrast is susceptible of explanation. I have ventured to regard the two antipodal floras thus compared as the favoured heirs of the ante-Glacial high northern flora, or rather as the heirs who have retained most of their inheritance. For, inasmuch as the present Arctic flora is essentially the same round the world, and the Tertiary fossil plants entombed in the strata beneath are also largely identical in all the longitudes, we may well infer that the ancestors of the present northern temperate plants were as widely distributed throughout their northern home. In their enforced migration southward, geographical configuration and climatic differences would begin to operate Perhaps the way into Europe was less open than into the lower latitudes of America and Eastern Asia, although there is reason to think that Greenland was joined to Scandinavia. However that be, we know that Europe was fairly well furnished with many of the vegetable types that are now absent, possibly with most of them. Those that have been recognised are mainly trees and shrubs, which somehow take most readily to fossilisation, but the herbaceous vegetation probably accompanied the arboreal. At any rate, Europe then possessed Torreyas and Gingkos, Taxodium and Glyptostrobus, Libocedrus, Pines of our five-leaved type, as well as the analogues of other American forms, several species of Juglans answering to the American forms, and the now peculiarly American genus Carya, Oaks of the American types, Myricas of the two American types, one or two Planer-trees, species of Populus answering to our Cotton-woods and our Balsam-poplar, a Sassafras, and the analogues of our Persea and Benzoin, a Catalpa, Magnolias, and a Liriodendron, Maples answering to ours, and also a Negundo, and such peculiarly American Leguminous genera as the Locust, Honey Locust, and Gymnocladus. To understand how Europe came to lose these elements of her flora, and Atlantic North America to retain them, we must recall the poverty of Europe in native forest trees, to which I have already alluded. A few years ago, in an article on this subject, I drew up a sketch of the relative richness of Europe, Atlantic North America, Pacific North America, and the eastern side of temperate Asia in genera and species of forest trees (*Am. Journ. Sci.* iii. vi. 85). In that sketch, as I am now convinced, the European forest elements were somewhat under-rated. I allowed only 33 genera and 85 species, while to our Atlantic American forest were assigned 66 genera and 155 species. I find from Nyman's Conspectus that there are trees on the southern and eastern borders of Europe which I had omitted, that there are good species which I had reckoned as synonyms, and some that may rise to arboreal height which I had counted as shrubs. But on the other hand and for the present purpose it may be rejoined that the list contained several trees, of as many genera, which were probably carried from Asia into Europe by the hand of man. On Nyman's authority I may put into this category *Cercis Siliquastrum*, *Ceratonia Siliqua*, *Diospyros Lotus*, *Styrax officinalis*, the Olive, and even the Walnut, the Chestnut, and the Cypress. However this may be, it seems clear that the native forest flora of Europe is exceptionally poor, and that it has lost many species and types which once belonged to it. We must suppose that the herbaceous flora has suffered in the same way. I have endeavoured to show how this has naturally come about. I cannot state it more concisely than in the terms which I used six years ago.

"I conceive that three things have conspired to this loss of American, or as we might say, of normal types sustained by Europe. First, Europe, extending but little south of lat. 40°, is all within the limits of severe glacial action. Second, its mountains trend east and west, from the Pyrenees to the Carpathians and the Caucasus beyond; they had glaciers of their own, which must have begun their work and poured down the northward flanks while the plains were still covered with forest on the retreat from the great ice forces coming from the north. Attacked both on front and rear, much of the forest must have perished then and there.

"Third, across the line of retreat of whatever trees may have flanked the mountain ranges, or were stationed south of them, stretched the Mediterranean, an impassable barrier. . . . Escape by the east, and rehabilitation from that quarter until a very late period, was apparently prevented by the prolongation of the Mediterranean to the Caspian, and probably thence to the Siberian Ocean. If we accept the supposition of Nordenskjöld that, anterior to the Glacial period, Europe was 'bounded on the south by an ocean extending from the Atlantic over the present deserts of Sahara and Central Asia to the Pacific,' all chance of these American types having escaped from and re-entered Europe from the south and east seems excluded. Europe may thus be conceived to have been for a time somewhat in the condition in which Greenland is now. . . . Greenland may be referred to as a country which, having undergone extreme glaciation, bears the marks of it in the extreme poverty of its flora, and in the absence of the plants to which its southern portion, extending six degrees below the Arctic circle, might be entitled. It ought to have trees and it might support them. But since their destruction by glaciation no way has been open for their return. Europe fared much better, but has suffered in its degree in a similar way" (*American Journal of Science*, *l.c.*, p. 194).

Turning to this country for a contrast, we find the continent on the eastern side unbroken and open from the Arctic circle to the tropic, and the mountains running north and south. The vegetation when pressed on the north by on-coming refrigeration had only to move its southern border southward to enjoy its normal climate over a favourable region of great extent; and, upon the recession of glaciation to the present limit, or in the oscillations which intervened, there was no physical impediment to the adjustment. Then, too, the more southern latitude of this country gave great advantage over Europe. The line of terminal moraines, which marks the limit of glaciation, rarely passes the parallel of 40° or 39°. Nor have any violent changes occurred here, as they have on the Pacific side of the continent, within the period under question. So, while Europe was suffering hardship, the lines of our Atlantic American flora were cast in pleasant places, and the goodly heritage remains essentially unimpaired.

The transverse direction and the massiveness of the mountains of Europe, while they have in part determined the comparative poverty of its forest vegetation, have preserved there a rich and widely distributed Alpine flora. That of Atlantic North America

[1] An Address to the Botanists of the British Association for the Advancement of Science; read at Montreal to the Biological Section, August 29, 1884, by Prof Asa Gray. Continued from p. 235.

leading to the interior of Central Asia. This road is much shorter than the usual route, but was considered until very lately as the worst and most difficult. But upon examining the obstacles presented by the road, and principally the alleged impossibility of effecting a passage through Mertvy, Koultouk, Oust-Oust, &c., M. Beliaffsky found the assertion to be erroneous, and therefore pronounces himself in favour of the road he has explored. In order to render it still more easy, he proposes that regular communication should be established on the Caspian Sea between Astrakhan and Cesarewitch Bay, that two light-houses, at least, should be constructed; that a steam navigation service should be established on the Amu-Doria, and a road practicable for vehicles made through the sands between the Amu-Doria and Khiva.

THE last (xi.) of Mr. Lansdell's series of interesting letters from Central Asia in the *Times*, describes his journey by boat down the Oxus, from Charjui to Khiva. In referring to the fish of the Oxus, he mentions the *Scaphyrincus*, a kind of sturgeon, the discovery of which in Central Asia, a few years ago, made quite a flutter among the students of ichthyology by reason of its resemblance to one of the North American sturgeons, which was found for a long time in the Mississippi only, until Fedchenko discovered one in the Syr Daria, and subsequently M. Bogdanovitch found another species in the Lower Oxus. The Oxus fish is known as *Scaphyrincus kaufmanni*. M. Bogdanovitch points out its interest from a geological point of view. "In the Palæozoic period," he says, "the ganoid fishes used to inhabit all the waters of the world in a great number of forms, comprising almost entirely the ichthyological fauna of that period. At the period of the Devonian formation this group of fishes seems to have reached its highest development, and in the strata of this formation are preserved the most numerous remains of its representatives. In the succeeding geological period this group appears to fall and die out, giving place to a group of *Teleostei* or bony fishes, which inhabited at that time all the waters of the world in a number of forms."

ON December 3, 1884, was celebrated, in the Scandinavian kingdoms, the bi-centenary of the birth of Ludwig Holberg, "the northern Molière." Prof. Erslev took advantage of the occasion to bring to the notice of the Danish Geographical Society the services to geography of the great dramatic poet in his generation. When Holberg was appointed Professor of History and Geography in 1730, the latter science was in a bad plight everywhere, and especially in Denmark. According to the curriculum, the Professor had to hold a reading once a fortnight on geography, but it is not known whether these readings actually took place. Holberg's great interest in geography is evident, not only from his own geographical writings, but also from many of his observations elsewhere. He betook himself with much eagerness to the study of the subject; in a preface to Van Howen's "Journey to Russia" (1743) he recommends others to write similar descriptions of their journeys. His first geographical work was a description of Denmark and Norway (1729), the second "An Account of the Principal Norwegian Commercial City, Bergen" (1737), which may be useful even still. His third work was a geographical book in Latin, entitled "Ludovici Holbergii Elementa Geographicum in usum Sudiosi Juventulis," of which several editions both in Copenhagen and Leipzig. It was translated into English in 1758, with a preface history by Holberg. Some editions of it have become of bibliographical rarities. His work was continued by Pastor Jonge, but Holberg's fifty volumes grew into seven large quarto volumes.

how Europe lost so much of its portion of a common inheritance, it only remains to consider how the western side of North America lost so much more. For that the missing types once existed there, as well as in Europe, has already been indicated in the few fossil explorations that have been made. They have brought to light Magnolias, Elms, Beeches, Chestnut, a Liquidambar, &c. And living witnesses remain in the two Sequoias of California, whose ancestors, along with Taxodium, which is similarly preserved on the Atlantic side, appear to have formed no small part of the Miocene flora of the Arctic regions.

Several causes may have conspired in the destruction;—climatic differences between the two sides of the continent, such as must early have been established (and we know that a difference no greater than the present would be effective); geographical configuration, probably confining the migration to and fro to a long and narrow tract, little wider, perhaps, than that to which it is now restricted; the tremendous outpouring of lava and volcanic ashes just anterior to the Glacial period, by which a large part of the region was thickly covered; and, at length, competition from the Mexican plateau-vegetation,—a vegetation beyond the reach of general glacial movement from the north, and climatically well adapted to the south-western portion of the United States.

It is now becoming obvious that the Mexican plateau vegetation is the proximate source of most of the peculiar elements of the Californian flora, as also of the southern Rocky Mountain region and of the Great Basin between; and that these plants from the south have competed with those from the north on the eastward plains and prairies. It is from this source that are derived not only our Cacteæ but our Mimoseæ, our Daleas and Petalostemons, our numerous and varied Onagraceæ, our Loasaceæ, a large part of our Compositæ, especially the Eupatoriaceæ, Helianthoideæ, Helenioideæ, and Mutisiaceæ, which are so characteristic of the country, the Asclepiadeæ, the very numerous Polemoniaceæ, Hydrophyllaceæ, Eriogoneæ, and the like.

I had formerly recognised this element in our North American flora, but I have only recently come to apprehend its full significance. With increasing knowledge we may in a good measure discriminate between the descendants of the ancient northern flora and those which come from the highlands of the south-west.

BRYN MAWR COLLEGE

THIS College is an Institution for Women, founded by the late Dr. Joseph W. Taylor; the following account of its foundation and objects, from the *Philadelphia Ledger*, has been kindly forwarded to us by Prof. Sylvester.

The work on the buildings and other preparations for the opening of the College are being pushed forward as expeditiously as possible, so that everything will be ready by June next. This new educational institution, it will be remembered, was founded by the late Joseph W. Taylor, M.D., a prominent member of the Society of Friends, of Burlington, N.J., who bought the land—about thirty-two acres—and began the erection of the college buildings in 1879. He died in January, 1880, leaving an endowment of 800,000 dols. for the continuance of the work he had begun—the erection and starting of a college for women.

By the terms of the will of the founder, the Trustees are members of the Society of Friends, but the students may be of any denomination, and their religious belief is to be respected. It was part of the purpose of Dr. Taylor to give to women of intelligence and refinement the best opportunities for culture, combined with Christian influences and social amenities. Scholars under sixteen years will be ineligible for admission. The Board of Trustees consists of: President—Francis T. King, of Baltimore, Md.; Charles S. Taylor, Burlington, N.J.; James C. Thomas, Baltimore, Md.; James E. Rhoades, Philadelphia; James Whitall, Philadelphia; John B. Garrett, Bryn Mawr, Penn.; Charles Harteshorne, Philadelphia; David Scull, Jr., Philadelphia; William R. Thurston, New York City; Albert K. Smiley, Lake Mohonk, N.Y.; Francis R. Cope, Philadelphia; Philip C. Garrett, Philadelphia, and Edward Bittle, Philadelphia.

As Dr. Taylor did not wish the college named after him, the Trustees have given the title of Taylor Hall to the main building in commemoration of his munificent bequest. This building

personal observations made during his tenure in 1883 of a medical official post in the country of these tribes, who live under the French protectorate, and occupy an immense territory of Barbara, lying between 32° and 33° 20′ N. lat. and 0° 40′ and 1° 50′ E. long. After giving a summary of the principal historical events connected with this people, who lay claim to being the sole representatives of the pure Berbers in Algiers, Dr. Amat enters at great length into the consideration of the results obtained by his careful anthropometric examination of fifty natives of Ghardaia. From the means of these determinations it would appear that the M'Zabites are of generally lower stature, and have less delicately proportioned limbs and features than the Arabs, but that, like the latter, they are often perfectly white in infancy, while light-coloured hair and beards are occasionally met with among the adults. The people are under the government of a religious or teaching body, composed of a powerful caste of learned clerks, or *tolbas*. The practice of interring food and domestic utensils with the dead points to usages of more ancient date than those of the form of Islamism which they follow. Unlike the genuine Arabs, they migrate in large numbers to the cities, where they conduct prosperous mercantile businesses, while they are the great corn purveyors of the Sahara. They employ among themselves a special form of language, which is a Berber dialect with certain affinities to the Kabyle, and is not a written tongue. The form of Islamism followed is that known as Owahbite Ibadite.—The concluding part of M. Denicker's notes on the Kalmuks. The author here treats of the special form of Buddhist Lamaism followed by the Kalmuk tribes, their hierarchy, mythology, rituals, religious festivals, objects of worship, and the special forms under which Cakya, Mowni, and others of their most highly-venerated so-called *burkans*, are worshipped. Owing to the comparatively late adoption of Buddhism, the Kalmuks have retained in their epic poems, aphorisms, and folk-lore, of which examples are given, more of the primitive Mongolian character than some of their kindred; but the Russian Kalmuks, like their brethren in China, are rapidly losing the warlike and aggressive spirit of their ancestors under the levelling systems of government to which they are subjected in both empires.—On the horizontal plane of the cranium, by E. Goldstein, with tables giving the variations and differences determined among persons of different races. These tables, which are remarkable for their voluminous and detailed character, will be found of great use in studying the causes of the angular variations observable in various ethic groups, and in the anthropoids, and in determining how far such deviations from a fixed horizontal line are dependent on race, age, or disease.

Bulletins de la Société d'Anthropologie de Paris, tome vii., fasc. 3, 1884.—M. de Ujfalvy's report of the results obtained by Dr. Lenhossek and others from an examination of the ancient Magyar tumuli, laid bare on the reconstruction of the town of Szegedin after the inundations of 1879.—On the age and character of the covered *allées* of dolmens on the plain of Ellez, near Tunis, by M. Girard de Rialle. The report is based on the communications of M. Poinssot.—On the presence of *Elephas primigenius* in the alluvial Chelles-beds, by M. Chouquet, who does not consider the juxtaposition of fossil remains as a proof of contemporaneity, but rather as the result of distinct depositions, which frequently belong to different geological periods.—Communication by M. D'Acy on the mammoth of the Cromer forest beds.—On the caves of Saumoussay, near Saumur, by M. Bonnemère, whose opinion that they are of pre-Roman date is opposed by M. Drouawlt and others.—On the exploration of the caves of Muikow in Cracovia, by M. Zaborowski. The authenticity of the supposed "finds" of Muikow is forcibly called in question by MM. Mortillet, Szambatty, and other local authorities.—Notes on the anthropological characters of California, by M. Ten Kate, who has here given the results of the cephalometric and other measurements made by him in his explorations, in 1883, of the districts of California south of 24° 40′ N. lat. The crania examined were of a well-marked Melanesian character, dolichocephalous, with moderate prognathism.—On a supplementary part of the great pectoral muscle, by M. Chudzinski.—On the influence of climate and race on the normal temperature of the human body, by Dr. Maurel. The results deduced from carefully tested determinations seem to be that the temperature of Europeans in intertropical and equatorial regions is raised only about 0° 30′ above its normal range in Europe, but that the mean temperature of certain races, as the Hindoos, is about 0° 50′ higher than that of Europeans.—On a gorilla fœtus, by M. Denicker. The subject was a female resembling in its pose and its thoracic development a human fœtus of five or six months. The lower members presented the true gorilla character.—On the antiquity of the Dingo in Australia, by M. Zabrowski.—On the case of a living double monstrosity, by M. Fourdrignier.—On cephalometric determinations of certain murderers who had been executed, as compared with measurements yielded by an equal number of persons distinguished for excellence of character or attainments, by Dr. Bajenoff.—On the first rudiments of infantine speech, by Dr. Allaire. The author considers that six distinct periods are observable in the development of the powers of speech, which are dependent on the successive processes of suction, digestion, dentition, &c., labial sounds being first emitted, while the dentals are acquired after the gutturals and nasals.—On recent German views regarding the cradle of the Aryan races, by M. Ujfalvy.—On the depopulation of the Marquisas, by M. Clavel, who considers that the general change of habits, and the cessation of intertribal wars, with its attendant decrease of activity, which have resulted from their contact with Europeans, must, rather than alcoholism of which he has seen no genuine cases, be accepted as the real factors in the rapid diminution of population that is going on in the Polynesian archipelago.—Note on the chariots of war employed by the Gauls, by M. Pétriment.—On the significance of the annual festival of the Indian Arikaris of Dokata, by Dr. Hoffman.—On the pathological characteristics of the Mandinguis of the Ouolof country, by Dr. Tautain.—On the "*Couvade*," by Dr. Maurel. The writer, on the authority of Dr. Lenoël of Amiens, asserts that this usage exists at the present day among the Indians of Guyana, near the Amazon.

Reale Istituto Lombardo, November 13, 1884.—The paintings of the Italian masters in the public museums of Europe, by Prof. G. Mongeri.—On the projected Penal Code for Italy, by Prof. A. Buccellati.—On the secular variation of the elements of terrestrial magnetism at Milan, by Ciro Chistoni.—On the total eclipse of the moon, October 4, 1884, by Prof. G. Celoria.—Meteorological observations made at the Brera Observatory, Milan, during the months of August and September, 1884.

November 27.—Experimental studies on the antiseptics of tubercular virus, by Prof. G. Sormani and Dr. E. Brugnatelli.—Successful treatment of a large tumour of twenty-two years' standing in the left side of a patient forty years of age, by Dr. G. Fiorani.—On the geometrical movement of the invariable systems, by Prof. C. Formenti.—The paintings of the Italian masters in the public museums of Europe (continued), by Prof. G. Mongeri.—Meteorological observations made at the Brera Observatory during the month of October 1884.

Jahrbücher für wissenschaftliche Botanik, herausgegeben von Dr. N. Pringsheim, Band xiii., Viertes Heft.—"Beiträge zür Morphologie und Physiologie der Meeresalgen," by G. Berthold, contains detailed investigations of the heliotropism of marine Algæ; also of the influence of other factors upon their structure and mode of growth, together with a description of certain means by which marine Algæ protect themselves from too great intensity of light, *e.g.* (1) by hair-like organs, of which the author distinguishes three types; (2) by peculiar formations in the protoplasm of individual cells: the most highly developed structures of this order are found in the genus *Chylocladia*, where one is to be seen in each of the peripheral cells of the thallus, and appears as a highly refractive, plate-like mass in close apposition with the outer wall. Reactions show that these structures consist chiefly of a substance of a proteid nature.—"Ueber die Wasservertheilung in heliotropisch gekrummten Pflanzentheilen," by A. Thate. The author tests Kraus's view that in organs with positively heliotropic curvature the shaded side contains more water than the illuminated side; he concludes that such a difference in amount of water cannot be proved, though on the other hand it cannot be asserted that it does not exist, analytical methods being as yet too imperfect: at best only approximate results can be obtained by Kraus's method.

Band xiv., Erstes Heft.—"Beiträge zur Entwickelungsgeschichte einiger Inflorescenzen," by K. Göbel. This article is chiefly devoted to the study of the development of the inflorescence in the *Gramineæ*. The author finds that, as regards their symmetry, the different varieties of inflorescence in this order cannot be referred to one type, but to two, the dorsiventral and the radial.—"Ueber Bau und Funktion des pflanzlichen Hautgewebesystems," by M. Westermaier, suggests as an important function of the epidermis that it shares with the vascular

system in the supply of water to the internal tissues, forming a complete peripheral mantle of aqueous tissue.—"Ueber Poren in den Aussenwänden von Epidermiszellen," by H. Ambronn. An attempt to show that the origin of pits in the outer walls of epidermal cells is referable to undulations in the young walls, and that these pits are not to be regarded as the functional equivalents of those in the walls of internal tissues.—"Nachträgliche Bemerkungen zu den Befruchtungsact von Achlya," by N. Pringsheim. A further contribution to the controversy as to the sexuality of the Saprolegniæ.

Zweites Heft.—"Ueber das Vorkommen von Gypskrystallen bei den Desmidieen," by Alfred Fischer. An investigation of the crystals of Calcium sulphate already known to exist in *Closterium*; similar bodies are also found in other genera of Desmids. In *Staurastrum*, *Desmidium*, and *Hyalotheca* they are not found. The author concludes that they are to be regarded as an excretory product; when the quantity produced is small, it may remain dissolved in the cell-sap; when larger it appears as crystals.—"Ueber farbige körnige Stoffe des Zellinhalts," by P. Fritsch. This article deals with the "anatomical structure" of colouring granules, exclusive of chlorophyll, and without reference to their development. In the light of recent discoveries the chief interest of such bodies centres in their development, and their relation to the chlorophyll granules.—"Die Zelltheilung, und das Gesetz der Zelltheilungsfolge von Melosira (Orthosira Thwaites) Arenaria Moore," by Otto Muller. A careful investigation of the succession of divisions as seen in this filamentous Diatom, which will throw light upon the process of multiplication of cells in other members of the group.

Drittes Heft.—"Untersuchungen über die Homologien der generativen Produkte der Fruchtblätter bei den Phanerogamen und Gefässkryptogamen," by L. Celakovsky. The author brings evidence from teratological specimens to bear upon the question of the homology of the integuments of the ovule with the indusium of the Fern-Sorus, with the object of establishing that homology.—"Untersuchungen über die Morphologie und Anatomie der Monokotylen-ähnlichen Eryngien," by M. Möbius. The main results of this investigation are that the similarity of the parallel-nerved species of Eryngium to the Monocotyledons lies only in the leaves and rhizomes; that it extends, however, beyond mere external characters, and may be recognised in the anatomical structure.

Bulletin de la Société des Naturalistes de Moscou, 1884, No. 1.—On the calculation of the average figures of relative wetness, by K. Weihrauch (in German). The author shows that the averages calculated by a mere addition of the observed values of $\frac{l}{d}$ do not give correct figures, and advocates a calculation consisting of an addition of all numerators (l) and of all denominators (d) separately, before making the division. He illustrates his method by several examples taken from the series of observations in the Caucasus.—The paper will be continued.—What becomes of bile in the digestive tube? by Dr. A. Weiss (in French). The author confirms to some extent the well-known opinion of Prof. Schiff.—Materials for the flora of the Government of Tamboff, district of Tamboff, by Th. Ignatieff. The steppe flora is characteri ed, as usual, by the *Stipa pennata*, but the following plants, showing a passage towards a more southern flora, are met with:—*Adonis vernalis*, *Verbascum Phœniceum*, *Echium rubrum*, *Muscari leucophæum*, *Iris furcata*, *Fritillaria ruthenica*, and *Salsola multiss.* All these, which do not extend much north—they are not met with in the Moscow flora—are remarkable for the most vivid coloration of their flowers. The author gives a list of 464 plants found at Exthal.—Review of the generative organs of the males of Bombus, by General Radoszkowski (in French), with four plates.—Short description of a journey to Central Asia, lecture by N. Somkine (in French). The author adds to his paper a very interesting chromolithographed picture representing a *saksaoul* forest (*Aboisaix ammodendron*, Ledebour) of the Kyzyl-koumis deserts. It is for the first time that we find in print so good a representation of this plant as it covers the *bar-khans*, or sandy downs, of the Steppe.—Researches into the histology of the hair, the bristle, the prickle, and the pen, by W. Lwoff (in German), with four plates.—Notice on the hypotheses as to the origin of Lake Baikal, by W. Dybowsky (in German). The recent discovery in Lake Baikal of the very same sponge (*Ladenietzkia baccalensis*) which is met with in the Bering Sea leads to the conclusion that it has immigrated into Lake Baikal from this sea. On the other side, several explor of Siberia, and recently again M. Cherski, have shown t there are no traces of a marine communication of Lake Bai with the sea during and since the post-Pliocene period; t there are very numerous traces of large lakes connected forme by broad rivers, and it would seem probable that the spon might have immigrated by this way. Dr. Dybowsky leaves t question open.

Bulletin de l'Académie Royale de Belgique, November 1884.—On certain phenomena of reduction produced in gra when germinating, and on the formation of diastase, by M. Jorissen.—On the quadrilinear form and surfaces of the thi order, by Prof. C. Le Paige.—Verbal communication on t phenomenon of stellar scintillation, by Ch. Montigny.—On t advanced vegetation observed in the spring of 1884 at Lon champ-sur-Geer, by Baron de Selys Longchamps.—On t chemical composition of krokydolite, and on the fibrous qua of South Africa, by A. Renard.—On the Chinese philosophe Lao-tse, a predecessor of Schelling in the seventh century, a by M. C. de Harlez.—An ambassador of the Duke of Alenç at the court of Queen Elizabeth, by Baron Kervyn de Lette hove.—On a portrait of Van Dyck's grandmother in the E Gallery, Modena, by Henry Hymans.

Atti della R. Accademia dei Lincei, July 1884.—On the e existence of different empirical formulas, and in particular those containing the capillary constant of fluids or the cohesi of solids, by Adolfo Bartoli.—Report of the committee a pointed to rearrange the Corsini Library recently acquired the Academy. This valuable library was found to compri altogether 39,082 works, including 5903 Elzevirians, Aldine and other old and rare editions, 2511 MSS. and 191 volumes music, besides 116 portfolios of engravings and 17,733 pri and drawings.—Meteorological observations made at the Roy Observatory of the Capitol during the month of June 1884.

Rivista Scientifico Industriale, October 31, 1884.—Variation in the electric resistance of solid and pure metallic wires and variations of temperature, by Prof. Angelo Emo.—Boulle pyrometer, described and figured by M. Lauth.—The gigant fossil turtle of Verona, described by S. Capellini.

November 15-30, 1884.—Variations in the electric resista of solid and pure metallic wires under variations of tempera (continued); part 2, original determinations of the electri resistance of the chief metallic wires under different tempe tures, by Prof. Angelo Emo.—On the oxidation of sulphur b ozone, by S. Zinno.—The Ammonites of the province of Vena described and figured by T. A. Catullo.

SOCIETIES AND ACADEMIES

LONDON

Geologists' Association, January 2.—On some recen views concerning the geology of the North-West Highlands, b Henry Hicks, M.D., F.G.S., President of the Association The author stated that as the *Proceedings* of the Associatio contained several papers dealing with the controversy concernin the rocks of the North-West Highlands of Scotland, he though it advisable to call the attention of the members to views co tained in an important article published in NATURE (p. 29) by the Director-General of the Geological Survey, and in a "Repor on the Geology of the North-West of Sutherland," by Messrs. Peach and Horne, in the same number, which cannot fail either to change entirely the future character of the controversy, or bring it rapidly to a satisfactory issue. Because of the positions held by the chief disputants on the one side, the controversy had assumed, to a great extent, the appearance of being one between official surveyors and some amateurs, who had been led to study the questions involved in it. The well-known and widely-accepted views first put forward by Sir R. Murchison, that there were clear evidences in the North-West of Scotland of a "regular conformable passage from fossiliferous Silurian quartzites, shales, and limestones upwards into crystalline schists, which were supposed to be metamorphosed Silurian sediments," were fully adopted by the official surveyors, including Sir A. C. Ramsay and Prof. Geikie, also by the late Prof. Harkness and others who had examined the areas. Prof. Nicol, of Aberdeen, however, for many years stoutly contested Sir R. Murchison's views, and maintained that they were based on erroneous observations. Unfortunately, at that time his views did not meet with much approval. In the year 1878 the author re-opened the contro

attention to some sections examined by him in
ch he maintained did not bear out the views of
on. He also suggested a modified interpretation
of Prof. Nicol. Since then many areas in Ross
have been examined by Mr. Hudleston, Prof.
allaway, Prof. Lapworth, and Prof. Blake, and
s showed that though differences of opinion pre-
points, yet all were agreed as to there being no
areas examined by them to support the Murchi-
a conformable upward succession. Many other
importance were brought out in these inquiries.
pressed gratification at the candid manner in
e question had been dealt with by the Director-
e Surveyors in their recent report, and at their
knowledging, after due examination in the course
d mapping parts of the areas referred to, that they
"evidence altogether overwhelming against the
ion which Murchison believed to exist."

BERLIN

gical Society, December 12, 1884.—Prof. Eulen-
on investigations into the sense of temperature,
which he had instituted specially for diagnostic purposes. As a test of the cutaneous perceptions in this respect, the only method available in practice was that of ascertaining the least differences perceived, and for this purpose the speaker had constructed special instruments which could be used to examine the sense of pressure as well as of temperature on the part of the skin. These instruments he laid before the Society. The apparatus for testing the sense of temperature consisted of two mercurial thermometers fastened on a transverse piece, with flat discoid tubes, one of which was fixed, the other movable. The fixed tube was surrounded at its lower part with metallic wires, by means of which, and an electric current, it could be warmed at pleasure. Both were placed beside or after one another on the spot to be examined, and the least difference of temperature which could be perceived was ascertained. When the temperature of the skin was below 27° C., its sensitiveness both to heat and cold was too obtuse for available results to be attained. In order to determine a normal scale above this limit, Prof. Eulenburg carried out a large number of measurements, which resulted in showing a great diversity in sense of temperature at different parts of the body. The sensitiveness to warmth was highest at the forehead and at the dorsal side of the last phalanges. At both these places differences of 0·2° C. were distinctly perceived. The least sensitiveness to warmth, on the other hand, was shown at the higher end of the anterior side of the upper part of the thigh, at the epigastrium, and in the median line of the back. At these places, only differences as large as from 0·9° C. to 1·1° C. were perceived. Sensitiveness to cold was likewise greatest at the forehead, and least at the epigastrium and back, but the degree of sensitiveness to cold did not always coincide with that of thermal sensitiveness at particular parts of the body, certain spots showing more sensitiveness to differences of heat, others to differences of cold. From the circumstance that the sense of temperature was more developed in the hands and face, which were exposed, than in those parts usually covered, and so far protected from variations, the speaker thought he was justified in inferring that the more delicate sense of temperature was an acquired sense. It was a striking fact that the tip of the tongue, so keen to mark variations of taste, was very dull in distinguishing variations of temperature. While engaged in these investigations Prof. Eulenburg became acquainted with the labours of Dr. Goldscheider, who, in the same manner as Herr Blix had done somewhat earlier, but, independently of this gentleman, came to the conclusion, as the result of a series of experiments, that the perceptions of temperature on the part of the skin had their seat in a large number of distinct cold and warmth points distributed over the whole body in definite complicated arrangement, the former of which (the cold points), under chemical as well as under electrical and mechanical stimulus, generated only the feeling of cold, the latter, under the same stimuli, only the feeling of warmth; that at all parts of the body there were a number of cold points which were easy to identify, and which were called cold points of the first class; and that, in addition, there were a larger number of cold points, more difficult to identify—cold points of the second class. Prof. Eulenburg repeated Dr. Goldscheider's experiments, and found them generally confirmed. He had further studied the distribution of the warm and cold points, both in himself and other persons, in such a manner that he marked with a fine pencil on the skin each warm or cold point found during examination, and then had an impression of the points so found made on wax paper, which he had laid over them. As a result of this operation it appeared that the forehead and the dorsal side of the phalanges had the most, the epigastrium the fewest, cold points. If the same spot of skin were examined on different days, the cold points of the first class always remained the same, while those of the second class varied, being found in larger number on one day than another. This diversity on different days appeared to coincide with the changes of temperature in the skin. The same relations held good in regard to the warmth points, which were separated locally from the cold points by tracts thermally insensible. The distribution of cold and warm points was not the same on all parts of the body. In some places the number of cold points predominated, in others the number of warm points. In the back of the hand, near to the wrist, for example, the number of warm points was in a majority, while towards the fingers the number of cold points preponderated. On comparing symmetrical parts of the body, it appeared that neither in number nor in the way in which they were distri-

noted did the cold points on one side resemble those on the other. Prof. Eulenburg further confirmed Dr. Goldscheider's conclusions that in particular parts of the skin, between the cold and warm points, lay the points of pressure which were sensitive to touch but not to differences of temperature. The existence, on the other hand, of special points for perceiving pain due to temperature the speaker had been unable to verify. Under the stimuli inadequate to temperature feeling, as the electrical and mechanical, he had tried the electric current with positive results. A moderate stream, producing in the skin the well-known prickly feeling, having by means of a pointed electrode been introduced into a cold point, generated a decided feeling of cold. Mechanical stimuli, which should produce the same effect, failed, however, in Prof. Eulenburg's experiments to do so.

Physical Society, December 19, 1884.—Prof. Lampe gave some interesting historical notes on the calculations respecting solids of attraction, the results of which he had communicated at the sitting of November 21. In these problems he had started with a solid of greatest attraction, in regard to which Gauss had laid down the law that its attraction was related to that exercised by the same mass in globular form on a point of its surface, as $3:\sqrt[5]{25}$. This law was found briefly adduced in a note in Gauss's treatise on capillarity, without any proof either there or anywhere else. Although Prof. Schellbach, who in 1845 calculated the form of the body of greatest attraction, ascribed the adduced law to Gauss, yet Prof. Lampe, in consideration that Gauss did not prove the law referred to and introduced it with the word "constat," was of opinion that it must have been already proved before the time when it was cited by Gauss. He had now, then, in point of fact, succeeded in tracing the author of the law. It originated, namely, with John Playfair, who, in 1809, in a treatise "On the Solid of Greatest Attraction," had calculated the form of such a body, and with reference to the magnitude of its attraction had arrived at the result already stated. In the same treatise John Playfair had dealt with a part of the problems brought before the Society by Prof. Lampe, and in respect of the cone and cylinder had come to the same results as himself. In calculating, however, the attraction of an ellipsoid flattened at the poles, he had, as was shown more at large by the speaker, committed an error, in consequence of which he had arrived at the conclusion that in the case of any eccentricity of the meridians the attraction was less than in the case of eccentricity 0, that is, than in the case of a globe. The fact, on the other hand, was that with oblateness the attraction at first increased and approached to that of the solid of greatest attraction, though yet without ever quite reaching it. It then diminished, till finally it sank to 0, when the pole coincided with the middle point. Let the attraction of a homogeneous mass in globular form be equal to 1, then the greatest attraction which this mass was in any case able to exercise was equal to 1·025986, while the maximum of attraction in an oblate rotatory ellipsoid was equal to 1·02213. Whether John Playfair's error had been already elsewhere observed or corrected was not known to the speaker. Altogether John Playfair's treatise appeared to have lapsed into oblivion, seeing that in the manuals of mechanics the law of maximum attraction being to the attraction of a ball as $3:\sqrt[5]{25}$ was universally imputed to Gauss, and the calculations of the solid of greatest attraction, which John Playfair had already worked out, to Schellbach.—Following up this address Dr. Krenig communicated the plan of an investigation which he contemplated carrying out in conjunction with Dr. Richarz. The investigation had for its object to determine with greater precision than had hitherto been done the mean density of the earth. The most exact measurements hitherto taken on this question came, as was known, from Herr von Jolly, in Munich, who, in a high tower, experimented on a balance, on one scale of which hung a wire, 21 m. long, bearing another scale at the bottom. After balancing a body in the upper scale and then transferring it to the scale 21 m. lower, the body was found to be somewhat heavier in the latter case in consequence of the more powerful attraction there exercised on it by the earth. On next placing under the lower scale a lead ball weighing 110 centner, and repeating the experiment, he found a greater increase on the upper scale weight than in the first instance. From the relation of these augmentations of weight and the volume and specific weight of the lead ball, Herr von Jolly calculated the mean density of the earth. Such a mode of measurement, however, laboured under this unavoidable source of error, that there was no means of safe-guarding the long wire from d erences of temperature. Dr. Krenig and Dr. Richarz had independently of each other, devised another method of uti the balance for the purpose of determining the mean de of the earth. Instead of placing the lead ball 21 m. under upper scale, they brought the heavy body directly under upper scale, whence a line, passing through a perforation of heavy mass, bore the lower scale immediately underneath When, now, a body was weighed in the upper scale, the ma lead acted in a sense similar to that of the force of gravity, its attraction was added to gravitation. When, on the other hand, a body was weighed in the lower scale, the ma lead operated in an opposite direction, and its attraction subtracted from gravitation. By this experiment, therefo double effect was obtained from the mass of lead instead of single effect in Herr von Jolly's experiment. Again, bringing a second equally large mass of lead under the of the other side, disposing it in the same manner as the mass, the effect of the mass of lead might be multiplied fold. An equilibration might be made by placing the we on one side in the upper, on the other side in the lo scale. Then the weights might be transposed. Inde deuly of the advantage of a fourfold comparative esti of the attraction of the mass of lead, all disturbances to differences of temperature were by this method enti obviated. The precision of the measurement would be further enhanced by using a mass of lead of 2000 cent The total mass of lead would compose a block, the most able form for which had yet to be theoretically determined. the centre, above this block, would stand the balance, and wires of both scales would pass through two equal perforati at the ends of which, under the block, would depend the lower scales. The construction of such a block of lead we be rendered possible by making it consist of 1300 sepa pieces capable of being joined together into the form desi and after a series of experiments they might be fitted up an so as to secure compensation for any errors due to unequal terior structure of the blocks. Of these masses of lead a pa lelopiped would have a side of 2·5 m. and a height of 1·5 As was self-evident, the precision of the balance was a ma of extreme moment for these measurements. The mecha who had undertaken their construction had engaged to prod a sensitiveness of one hundred millionth for the weight of 1 used in such measurements. He had further engaged, by adequate modification of the construction, to obviate the e arising from the circumstance that the edges never correspon mathematically with that term, but had always more or diameter, so that with the inclination of the beams the plan support changed. Dr. Krenig hoped to be able in the co of a year to announce the numerical results of the experiment

JAMES HOW & CO., 73, FARRINGDON STREET, LONDON.

THE CELEBRATED

Is unrivalled for Gardeners', Foresters', Farmers', Joiners', and Amateurs use. It requires no oil. Sharpen with a spittle or water. Puts on a keen, sharp edge; no humbug about this. Has stood the test of 100 years. Cut in Hones for Axes, Hedge Knives, Razors, Penknives, and Plane Irons, &c. Honourable Mention, Paris Exhibition, 1878; and Bronze Medal, London International Exhibition, 1884. Ask your Ironmonger or other retail house to get you one, and give my address; if he won't, drop me a note.
JOHN C. MONTGOMERIE,
Tam O'Shanter Stone Hone Works, Dalmore, Turbolton Station, R.S.O. Ayrshire.

HOLLOWAY'S OINTMENT AN INFALLIBLE REMEDY
For BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES and ULCERS. If effectually rubbed on the Neck and Chest, it cures SORE THROATS, BRONCHITIS, COUGHS and COLDS; and for GOUT, RHEUMATISM, and all Skin Diseases it is unequalled.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharine, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

NORTH BRITISH AGRICULTURIST,

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.
Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street, London, E.C.
Money Orders payable to CHARLES ANDERSON, Jun., Edinburgh.

AUTOTYPE PHOTOGRAPHIC BOOK ILLUSTRATION.

ADVANTAGES.

1st. They present Faithful Representations of the Subjects.
2nd. Printed on the paper of the Book itself, mounting not required.
3rd. For Editions of 1000 and under they are cheap.

Employed by the Trustees of the British Museum and by the Learned Societies; also by many of the leading Publishers.

Amongst the Works recently done, or at present in the press, may be cited: Lady Brassey's "Tahiti"; Prof. Gardner's "The Types of Greek Coins"; Hofmeyer's "Practice of Ornamental Turning"; Audsley's "Ornamental Arts of Japan"; Lockyer's "Spectral Analysis"; Burgess's "Archæological Survey of India"; "Samuel Palmer: a Memoir."

Of this last work the *Athenæum* says:—"This book is admirably illustrated by fourteen autotype reproductions from lovely and characteristic sepia drawings."

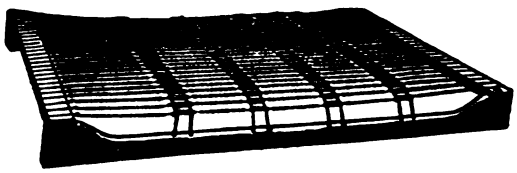
W. WATSON & SONS, 313, HIGH HOLBORN, LONDON.
TWO DOORS FROM CHANCERY LANE. ESTABLISHED 1837.

THE "EXCELSIOR"
PATENT SPRING MATTRESS.



AWARDS:
TEN PRIZE MEDALS,
FOURTEEN CERTIFICATES OF MERIT

The principle of arrangement permits the free movement of one sleeper without inconvenience to the other, admits of complete isolation of each, and *effectually prevents depression in the centre.*

THE "Excelsior" AND "Matlock" BED-RESTS.

THE "EXCELSIOR" & "MATLOCK" COUCHES.

Retail from Cabinet Makers, Upholsterers, &c.

THE NEW PATENT
WOVEN WIRE MATTRESS.

The leading peculiarity of this Mattress is the unique combination of a woven wire central portion with helical springs of great strength and reliable temper, giving advantages possessed by no other make. The helical springs obviate the tendency in all woven wire mattresses to become hollow and so cause sleepers to roll into the middle of the bed.

Illustrated Descriptive Circulars and Price Lists from

CHORLTON & DUGDALE, MANCHESTER.

The REMINGTON "PERFECTED" TYPE-WRITER.

A MACHINE to supersede the pen for manuscript writing, correspondence, &c., having twice the speed of the pen; is always ready for use, simple in construction, not liable to get out of order, easily understood. It is used in Government Offices, and by Merchants, Bankers, Lawyers, Clergymen, Doctors, Scientists, &c.

"The other advantages of the machine, those for which chiefly I personally value and employ it, are worthy of a moment's consideration. Its work in my hands is about twice as rapid as that of a pen, and became so after a few weeks of practice. I have worked the machine for eight consecutive hours without more than ten minutes' interruption, and at the end of that time my hands were not conscious of the least fatigue. Every writer is aware that the same thing cannot be said with regard to the pen.—ROBERT BRUDENELL CARTER, F.R.C.S., &c."

NO. 2 PERFECTED TYPE-WRITER.
CAPITALS AND SMALL LETTERS.

REDUCED PRICES.

The *Times*, Tuesday, September 11, 1883.

"The chief use of the type-writer may be said to be for business correspondence, for rapid and legible copying, as for the transcription of short-hand notes, and in the preparation of manuscript for the press or for revision. . . .

"In the preparation of manuscript for revision or for the press, the advantages of the type-writer over the pen are very decided. There is, first, the greater rapidity of production; and next, the superior quality of the product. The work of the type-writer is fairly comparable to a printed proof, and may be overlooked and revised with the same facility, any necessary alterations being made by interlineation with a pen. . . . Manuscript produced by the type-writer ought to go to the printer in almost precisely the condition in which it will finally appear."

BEEMAN & ROBERTS, Sole Agents, 6, King Street, Cheapside, London.

13 GOLD MEDALS. # THE "OTTO" GAS ENGINE. 16 SILVER MEDALS.

CONSUMPTION of GAS guaranteed to be 25 to 75 % less than ANY other Gas Engine per brake horse-power.

The Lectures will be on FRIDAYS at 4.
Introductory Lecture on February 6. Fee, £3 3s.

TALFOURD ELY, M.A., Secretary.

BROWNING'S PLATYSCOPIC LENS.

Engraved Real Size.

A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge*.
The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.
The Platyscopic Lens is made of four degrees of power, magnifying respectively, 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.
The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.
Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s.* 6*d. each power.*
Illustrated description sent free.

THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM

who has last week sent to his subscribers Cordylophora patens, with drawing and description. He has also sent out Trout ova, Uvella virescens, Lophopus crystallinus, Spongilla fluviatilis, Melicerta ringens, Brachionus amphiceros, Stentor polymorphus, Cordylophora lacustris; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Ten Parts, 1s. each.

C. D. AHRENS.

PRISM WORKER AND PRACTICAL OPTICIAN

36, GREAT RUSSELL STREET, LONDON, W.C

SPECIAL NOTICE.—See the New Polarising Prism.

Can be used over any A & B Eyepiece. Strongly recommended for Lantern Work; will take in any Object. Also see the New Erecting Microscope. Any Object-Glass and any Eyepiece can be used with it. It is the only way of seeing the Objects in their right shape and form. Maker of the Large Nicol Prism in existence for the late W. Sportiswoode, Esq., P.R.S., &c., &c., and for Frank Crisp, Esq., LL.D., B.A., &c., &c.

TRADE SUPPLIED WITH PRISMS.

SCIENCE AND ART DEPARTMENT

50 PER CENT. GRANT FOR THE PURCHASE OF STANDARD COLLECTIONS AND APPARATUS FOR TEACHING GEOLOGY AND MINERALOGY. NEW LISTS and FORMS on which the Application is to be made supplied by

THOMAS J. DOWNING,

Geologist, &c.,

38, WHISKIN STREET, LONDON, E.C. (over Quarter of a Century

SILVER MEDAL AWARDED

To JAMES R. GREGORY for

EDUCATIONAL COLLECTIONS OF GEOLOGY AND MINERALOGY

By the International Health and Education Exhibition, 1884.

Medals also Awarded in 1862, 1867, 1870, and 1883 in London, Paris, Dublin and London.

Specialities:—

GEOLOGICAL AND MINERALOGICAL COLLECTIONS For Museums, Colleges, Schools, Lectures, Students, &c.

Catalogues and Lists on application to—

JAMES R. GREGORY,

GEOLOGIST AND MINERALOGIST,

88, CHARLOTTE STREET, FITZROY SQUARE, W.

Established 1858.

BOOKS (Secondhand), Miscellaneous, Re

mainders, &c.—C. HERBERT, English and Foreign Booksellers, 32 Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parliament purchased.

NON-MAGNETISABLE WATCHES.

WATCHES which cannot be "MAGNETISED," constructed on the recommendation of W. CROOKES, Esq., F.R.S., and as exhibited at the Electrical Exhibition, Paris.

E. DENT & CO., Makers of the Primary Standard Timekeeper of the Royal Observatory, Greenwich.

Only Addresses:—61, Strand, and 34, Royal Exchange, London.

N.B.—Watches can be converted to this plan.

EDWARD WARD,

Preparer of Microscopic Slides and of Mounting Media.

WHOLESALE AND RETAIL

249, OXFORD STREET, MANCHESTER

(Nearly opposite Owens College).

Speciality—**SLIDES OF VOLCANIC DUST** from the Krakatoa Eruption 2s. each. Post Free, 2s. 2d.

UNMOUNTED OBJECTS FOR ARRANGING IN SERIES AT 3s. EACH SERIES.

List on Application.

LITHOGRAPHIC ILLUSTRATIONS

Of the highest class executed for Scientists in Entomology, Geology, Natural History, Antiquities, &c. Accurate Drawings made from Specimens either by the Microscope or to natural size.—W. PURKISS, 3, Featherstone Buildings, Holborn, W.C.

Now Ready, Part IV., Vol. XLVII., December 1884, Price 5s.

STATISTICAL SOCIETY'S JOURNAL.

CONTENTS.

"British and Foreign Colonies;" the Inaugural Address of Sir Rawson W. Rawson, K.C.M.G., C.B., President. Session 1884-85.
"Wine Production in France." By A. E. Bateman, Esq.
"The Comparative Efficiency and Earnings of Labour at Home and Abroad." By I. S. Jeans, Esq.
Miscellanea:—(1) Agricultural Returns for 1884. (2) Savings Banks Statistics. (3) The Forthcoming Industrial Remuneration Conference. (4) The Approaching Celebration of the Society's Jubilee. (5) Additions to the Library—Annual Index to Vol. 47—List of Members, Rules, &c.

London: EDWARD STANFORD, 55, Charing Cross, S.W.

Now Ready, price 6s., Vol. XIX. Part II., January 1885.

THE JOURNAL OF ANATOMY AND PHYSIOLOGY, NORMAL AND PATHOLOGICAL.

CONDUCTED BY

Professors HUMPHRY, TURNER, and M'KENDRICK.

Contents.

1.—Diseases of Reproductive Organs. By J. B. Sutton, F.R.C.S. (Plate VIII.)
2.—Oviduct in Adult Male Skate. By J. D. Matthews, F.R.S.E. (Plate IX.)
3.—Influences of some Conditions on Metamorphosis of Blow-Fly. By J. Davison, L.R.C.S.I.
4.—Sources and Excretion of Carbonic Acid at the Liver. By J. J. Charles, M.D.
5.—A Method of Maceration. By A. M. Paterson, M.B. (Plate X.)
6.—Floating Kidney. By David Hepburn, M.B.
7.—Movements of Ulna in Rotation of Fore-Arm. By T. Dwight, M.D.
8.—Dissection of a Double Monster (Epignathus). By A. Hill, M.B.
9.—Relation of Alveolar Form of Cleft Palate to Incisor Teeth and Intermaxillary Bones. By Prof. Turner, M.B.
10.—Dumb-Bell-shaped Bone in Palate of Ornithorhynchus compared with Pre-Nasal Bone of Pig. By Prof. Turner, M.B.
11.—The Infra-Orbital Suture. By Prof. Turner, M.B.
12.—Note on Oviducts of Greenland Shark. By Prof. Turner, M.B.
13.—Anatomical Notices.

MACMILLAN & CO., London.

THE BREWERS' GUARDIAN:

A Fortnightly Paper devoted to the Protection of Brewers' Interests, Licensing, Legal, and Parliamentary Matters.

REVIEW OF THE MALT AND HOP TRADES; AND WINE AND SPIRIT TRADE RECORD.

The Organ of the Country Brewers.

"The Brewers' Guardian" is published on the evenings of every alternate Tuesday, and is the only journal officially connected with brewing interests.
Subscription, 16s. 6d. per annum, post free, dating from any quarter-day Single Copies, 1s. each. Registered for transmission abroad.
Offices—5, Bond Court, Walbrook, London, E.C.

16s. per Ann., 20s. Post Free.

DER NATURFORSCHER.

Wochenblatt zur Verbreitung der Fortschritte in den Naturwissenschaften.

Herausgegeben von Dr. WILHELM SKLAREK.

A Weekly Periodical devoted to Natural Science. 52 Nos., 16s. Specimen Numbers may be had through any Foreign Bookseller. 1884 commenced the XVIIth volume.

Berlin: DÜMMLER, 77, Charlottenstrasse, S.W., and all Booksellers.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 28. Edited by W. von FREEDEN, M.R., Hamburg, Alexander Street, 8.

On the 1st of every Month.

JOURNAL OF BOTANY, BRITISH AND FOREIGN.

Edited by JAMES BRITTEN, F.L.S., British Museum.

CONTENTS:—Original Articles by leading Botanists.—Extracts, and Notices of Books and Memoirs.—Articles in Journals.—Botanical News.—Proceedings of Societies.

The MORPHOLOGY of the SKULL. By

W. K. PARKER, F.R.S., Hunterian Professor, Royal College of Surgeons, and G. T. BETTANY, B.Sc., Lecturer on Botany in Guy's Hospital Medical School. Illustrated. Crown 8vo. 10s. 6d.

MACMILLAN & CO., London.

NORTH BRITISH AGRICULTURIST,

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street, London, E.C.

Money Orders payable to CHARLES ANDERSON, Jun., Edinburgh.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations. Conducted by C. G. BARRETT, J. W. DOUGLAS, R. MCLACHLAN, F.R.S., E. C. RYE, F.Z.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s. each; the succeeding vols. may be had separately or together, at 7s. each.

London: JOHN VAN VOORST, 1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

Price Sixpence. By Post, Eightpence.

THE ENGLISH ILLUSTRATED MAGAZINE.

Contents for January.

1.—"A Normandy Milkmaid." Engraved by J. A. Quartley, from a Drawing by W. J. Hennessy. Frontispiece.
2.—"Calvados." By Mary Mather. With Illustrations by W. J. Hennessy.
3.—"Shakspeare's Country." By Rose Kingsley. With Illustrations by Alfred Parsons (To be continued.)
4.—"The Dramatic Outlook." By H. A. Jones. With Illustrations by Hugh Thomson. (To be continued.)
5.—"The Girl at the Gate." By Wilkie Collins. (To be continued.)
6.—That Terrible Man. Chapters VII., VIII., IX., X. By W. E. Norris. (Concluded.)
7.—A Family Affair. Chapters XI., XII. XIII. By Hugh Conway. (To be continued.)

MACMILLAN & CO., LONDON.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY

Edited by JOHN T. CARRINGTON,

With the Assistance of

FREDERICK BOND, F.Z.S. | JOHN A. POWER, M.D.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

Numerous WOODCUT ILLUSTRATIONS, to the printing of which especial attention is given, and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

HIGH-LEVEL METEOROLOGY

Bericht über die Errichtung der Meteorologischen Station auf dem Säntis und ihre Thätigkeit, September 1883 *to August* 1884. Erstattet von R. Billwiller. (Zurich, 1884.)

Journal of the Scottish Meteorological Society. Third Series, No. 1.

WE briefly noticed at the time (NATURE, vol. xxix. p. 413) M. Billwiller's first report on the Swiss high-level station on Säntis, in the Canton of Appenzell; and his second report has now come to hand, giving, along with a rapid history of the establishment of this first-class meteorological observatory and its equipment, an excellent *résumé* of two full years' observations, ending August 31, 1884. A comparison of the results with those obtained for Ben Nevis presents several points of considerable importance.

On Säntis, 8094 feet high, the mean annual atmospheric pressure is 22·237 inches, the highest monthly mean being 22·429 inches in August, and the lowest 21·993 inches in March. On Ben Nevis, 4406 feet high, the mean annual pressure is 25·257 inches, the highest mean being 25·400 inches in July, and the lowest 25·141 inches in January. The differences between the highest and lowest is thus 0·436 and 0·259 inch respectively. On Säntis the mean annual temperature is 28°·2, the highest monthly mean being 41°·4 in August, and the lowest 18°·0 in January. The annual mean for Ben Nevis is 30°·9, the highest monthly mean being 41°·3 in July, and the lowest 22°·0 in February. The lower mean temperature of Säntis is thus wholly due to its colder winters.

But the most marked difference in the climates of the two situations is revealed by the hygrometer. On Säntis the mean annual relative humidity for the two years is 84, the highest monthly mean being 93 in September 1882, and the lowest 71 in March 1884. On Ben Nevis, on the contrary, the lowest mean monthly humidity was 90 for May 1884, and the highest for January of the same year, when the mean dry bulb was 25°·50, and wet bulb 25°·47, showing an approximate humidity of 99. Indeed, so thick and continuous was the covering of mist, fog, and cloud in which Ben Nevis was wrapped during this month, that the difference between the mean coldest and warmest hour of the day in winter is only half a degree. We have drawn attention (vol. xxx. p. 336) to the sudden changes of humidity which characterise the climate of Ben Nevis in connection with anticyclonic movements, when the atmosphere passes rapidly from a state of the most complete saturation to a state of dryness greater than is ever reached at lower levels in this part of Europe, and that on such occasions the temperature rapidly rises, till sometimes it even rises higher than at Fort William, about 4400 feet lower down. Now M. Billwiller gives an extremely valuable column in one of the tables, showing the minimum relative humidity observed each month, from which we see that a humidity of 21 occurred in August 1883, and that on six of the other twenty-three months a humidity less than 30 was recorded. The importance of these observations from Ben Nevis and Säntis on the great movements of the atmosphere in cyclones and anticyclones, and on the Föhn and the various theories that have been suggested in explanation of its phenomena, need not here be insisted on.

On Säntis the annual rainfall, inclusive of melted snow, was 67·83 inches. The heaviest rainfall of any month was 15·12 inches in July 1883, and the lightest 0·71 inch in February of the same year. On the top of Ben Nevis, for the five months from June to October of 1882 and 1883, the mean rainfall was 44·35 inches; and on Säntis, for the same five months of 1883 and 1884, the rainfall was 43·95 inches—the summer rainfall of the two places being thus nearly the same. These amounts are very greatly in excess of what several theories of the distribution of the rainfall on the slopes and tops of mountains would lead us to expect. In discussions of this question it will be necessary to give more pointed attention than has yet been given to the great vertical movements in the atmosphere which are disclosed by the hygrometric observations of these high-level stations.

Of even greater interest are the hourly observations at the two observatories, especially those relating to atmospheric pressure and wind. At the two places the hourly curves of pressure for different seasons run closely parallel to each other. In June, when the more special features of the curves are most pronounced, they closely approximate to a single diurnal minimum and maximum. The minimum occurs from 5 to 6 a.m., and the maximum from 9 to 10 p.m., the daily range being 0·039 inch on Säntis, and 0·030 inch on Ben Nevis. Each curve shows an extremely shallow secondary minimum from 5 to 6 p.m. which, as compared with the secondary maximum immediately preceding indicates a fall not exceeding 0·003 inch.

This secondary maximum occurs at 3 p.m. on Säntis, and at 3.30 p.m. on Ben Nevis, and is the analogue of the morning maximum which occurs at lower levels in the same localities six hours earlier. On Mount Washington, United States, this maximum occurred in June 1873 at 8.30 a.m. at the base of the mountain, 2898 feet above sea-level, 10 a.m. at 4059 feet, 11 a.m. at 5533 feet, and at noon on the top of the mountain at a height of 6285 feet. On Ben Nevis, while pressure is steadily falling at the base of the mountain from 9 a.m. to 4 p.m., on the peak it continues steadily to rise; and the same phenomena doubtless obtain at Säntis.

At the same time the diurnal velocity of the wind on these peaks shows even a stronger contrast when compared with the diurnal velocity at lower levels. At low levels and on plateaux of considerable extent the velocity of the wind falls to the daily minimum early in the morning, and rises to the maximum at or immediately after noon, or about the time of strongest insolation. The following table, showing the diurnal variation in the wind's velocity on Ben Nevis, Säntis, and Mount Washington in summer, and on Ben Nevis in winter, presents for these elevated peaks curves precisely the reverse of the curves for velocity at lower levels. The figures express in percentages the excess or defect of each hour's velocity from the daily mean :—

	Ben Nevis June—Aug. 1884	Sierra June—Aug. 1884	Mt. Washington Mean—June, 1872	Ben Nevis Dec.—Feb. 1883—84

midnight	9	9	19	6

Hence the maximum occurs on these heights shortly after midnight, and the minimum shortly after noon. Now it will be seen that these diurnal maxima and minima occur nearer midnight and noon than do the phases of the other meteorological phenomena, thus suggesting a direct connection with solar and terrestrial radiation. It is singular that, while the diurnal period of strongest insolation determines the occurrence of the maximum velocity of the wind over extensive land surfaces, it determines the minimum velocity on peaks rising to a great height above the land surfaces surrounding them. Of special importance in its bearings on the question is the curve of diurnal variation on Ben Nevis for the three winter months of 1883-84, when the mean velocity of the wind was nearly double that of the summer months. In that season Ben Nevis was under a deep covering of snow, the sky clouded nearly the whole time, the air frequently darkened with dense drifting fogs, and the difference between the mean lowest and highest hourly temperature only half a degree. Notwithstanding the practical uniformity of temperature of the surface of the top of Ben Nevis during the twenty-four hours of the day, the curve of the diurnal variation in the wind's velocity was as clearly marked in winter as in summer, and the two curves were alike in showing the occurrence of the maximum shortly after midnight, and the minimum shortly after noon. We must therefore conclude that the peculiar type of the diurnal curves of wind velocity on these elevated peaks is altogether independent of the temperature of the surfaces over which the winds blow. The results point not obscurely to an investigation of the relations of the visible and invisible vapour of the atmosphere to solar and terrestrial radiation as an inquiry of first importance in meteorology.

OUR BOOK SHELF

Exercises in Electrical and Magnetic Measurement. By R. E. Day, M.A. New Edition. (London: Longmans, Green, and Co., 1884.)

Mr. Day has produced a new and considerably improved edition of a most useful and valuable little book. Every teacher of electricity whose work is not confined to the beggarly elements of mere phenomena will thank Mr. Day for the admirable selection of problems put together in this volume. Nothing could be a greater boon to the real student than the means thus afforded of testing his knowledge of the exact quantitative laws of the science. If it were not for the historic interest of that rather antiquated instrument—the torsion balance—we should doubt the utility of giving so much attention to it. Although the more modern electrometers have entirely superseded the torsion balance as an instrument of research and of measurement, it has, nevertheless, become so prominently fixed—like some grand old fossil long ago extinct—amongst the characteristic forms of electrical instruments, that examiners still expect candidates for examination to know something about it. On the other hand, the space allotted to moments of torsion and inertia is all too brief, though admirably filled. We must, however, take exception to the practice apparently followed on p. 62, of expressing a moment of couple in *dynes*: it should surely be *dyne-centimetres*. The section on the chemical (or rather thermo-chemical) theory of electromotive force is excellent. The problems comprised under the heading Electromagnetic Measurement are admirable, though perhaps a little beyond most students.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Earthquakes and Terrestrial Magnetism

Mr. W. H. Preece having written to the Astronomer-Royal to ask whether any disturbance of our magnets or our earth-current apparatus was experienced during the recent earthquake in Spain, it may be interesting to communicate also for the information of your readers the result of an examination of our photographic registers in consequence made, and especially in order that what has been remarked may, if possible, receive confirmation.

As respects magnetic movement, the magnets on Dec. 25 last and following days were generally quiet. But on looking more closely at the registers, attention was at once drawn to a small simultaneous disturbance of the declination and horizontal force magnets, occurring at 9h. 15m. on the evening of December 25. Both magnets were at this time set into slight vibration, the extent of vibration in the case of declination being about 2′ of arc, and in horizontal force equivalent to 1/001 of the whole horizontal force nearly. The movements have not the character of magnetic movements, and, if in reality produced by the earthquake, are of course simply an effect of the shock, the magnets being heavy bars suspended by silk threads some feet in length. About ten minutes afterwards there is doubtful indication in the horizontal force register of a second disturbance. There is no corresponding perceptible disturbance in the earth-current registers.

No other similar motion is observable either on December 25 or on the following days.

It may be remarked that in NATURE for January 1 last (p. 200) the time of occurrence of the earthquake at Madrid is said to be 8h. 53m. p.m. Taking this to be Madrid time, it corresponds to 9h. 8m. of Greenwich time. WILLIAM ELLIS

Royal Observatory, Greenwich, January 15

Teaching Chemistry

The subject of science-teaching in schools, and more particularly the best way in which practical chemistry should be taught, has of late been discussed in the columns of NATURE. With the editor's leave, I should like to say a little regarding the methods of teaching chemical science in general.

NATURE for January 8 contained notes, by Profs. Sir H. E.

Roscoe and W. J. Russell, on "Experiments suitable for Illustrating Elementary Instruction in Chemistry." These notes appear to me to be very useful as a rough guide to the school-teacher. But unless the teacher is able to arrange the experimental illustrations so that some conclusions regarding the elementary principles of chemistry shall be drawn from the results he obtains, which conclusions shall then be submitted to experimental examination, I think the notes will fail of their object.

It is to the want of progressiveness in the ordinary chemical course that I wish to draw attention.

The student of physics advances; he feels his way from one set of phenomena to another; he generalises, and gets hold of some principles on which he may rest. In the ordinary chemical course the student begins with enthusiasm; he is delighted with the experiments, and he takes a lively interest in the manipulative failures of the lecturer. But, after a little, the student finds that he is not progressing. When he has been told, and shown, the properties of hydrogen, oxygen, and water, he is expected to take as much interest as ever in hearing a list of properties of nitrogen and oxides of nitrogen. Then he fills his note-book with many facts regarding ammonia and nitric acid, and so on.

Now I do firmly believe that chemistry is a branch of science, and that it may be taught as such. I think it is possible, in a course of lectures on chemistry, to lead the fairly intelligent and not very idle student from simple facts about everyday occurrences to the difficult and apparently remote discussions regarding the architecture of molecules, in which chemists so much delight.

If lectures on chemistry were arranged so that principles should be discussed and amply illustrated by well-chosen experiments, instead of being (as I am afraid is still too often the case) repetitions of disconnected facts about a string of elements and compounds, I believe this branch of science would rapidly develop in this country. It seems to me that the distinction implied in the commonly-used terms *chemistry* and *chemical philosophy* is radically unsound. There are not two chemistrys, but one chemistry. We do not speak of physics as different from natural philosophy.

What we want is to convince our students that they are dealing with realities. I am continually presented with answers to questions, which perhaps demand a knowledge of the laws of chemical combination, wherein a few elementary facts are elevated to the rank of an all-embracing theory, and complex structural formulæ are dealt with in a style of appalling familiarity, as if they were the topics which it is necessary to discuss on the very threshold of chemistry. One is told that chlorine is a monad, that is, it is a "one-armed one"; and then the conclusion is triumphantly announced, "*thus we see why it is*" that hydrogen and chlorine combine to form hydrochloric acid, and so on. The other day I implored a candidate in a certain examination to give me a reason for writing the formula of alcohol C_2H_5—OH rather than C_2H_6O; he told me he had seen the former in a book. This is enough for the average student; and yet these people call themselves students of science. I am afraid the teachers are greatly to blame.

The examiners have undoubtedly much power; but I think the examinations in chemistry are improving as a whole.

When a lecturer in chemistry announces two series of lectures, one elementary and one advanced, is it not very often found that the advanced class is condemned to hear copious details regarding the purification and methods of separation of the rare metals, while the elementary class is entertained with an exhibition of the properties and reactions of the simple and compound gases? But is this chemistry?

I think that the teachers of chemistry must consent to abandon the time-honoured practice of placidly proceeding from element to element, and from compound to compound; they must ask themselves whether they know of any reasons why chemistry should be called a branch of natural science, and, having conscientiously answered this question, they must try to make their students really acquainted with these reasons.

Dr. Sydney Young (NATURE, vol. xxxi., p. 126) has referred to the paucity of good elementary text-books of chemistry. I, too, have felt the want of a really good book in attempting to teach the principles of chemistry to beginners. Is there any elementary book which treats chemistry as a genuine living science?

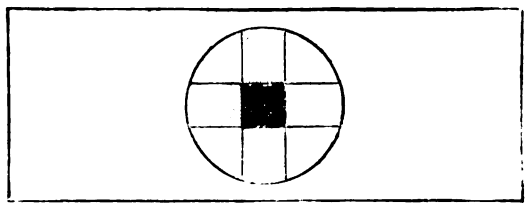
Cambridge, January 12

A Method of Isolating Blue Rays for Optical Work

IN many optical experiments, *e.g.* in examining the dispersion of optic axes in crystals, a homogeneous or monochromatic light is required. A fairly homogeneous red light, nearly corresponding to the Fraunhofer line B, can be obtained by a properly-selected piece of red glass placed in front of a good Argand burner or paraffin lamp. For yellow light, nothing can be better than the flame of a Bunsen's burner in which a bead of sodium carbonate is held in a loop of platinum wire. For blue rays, the light transmitted by a solution of cuprammonium sulphate is generally recommended, since the ordinary blue glass coloured with cobalt invariably transmits red rays as well as blue. But the use of a glass cell containing a strong ammoniacal solution is often inconvenient and unpleasant.

I have met with a peculiar kind of greenish-blue glass, used for railway signal lamps, and known as "signal-green glass" (coloured, I believe, with copper in its divalent condition), which is remarkably opaque to the less refrangible rays nearly as far as Fraunhofer's line E, while it transmits a large quantity of blue and some green light. By combining a piece of this glass with a piece of rather deep-tinted cobalt glass, the red rays transmitted by the latter may be wholly stopped, and only the part of the



spectrum between F and G is transmitted, constituting a light at any rate not less homogeneous than that transmitted by solution of cuprammonium sulphate.

This "signal-green glass" is also useful in illustrating selective absorption of light by different media. If, for instance, a piece of it is superposed on a piece of properly-selected red glass, each absorbs what the other transmits, and practically no luminous rays survive the two; only a faint neutral-tinted light struggling through, even when strong sunlight is used.

This can be well shown on the screen by fixing a narrow strip of the "signal-green glass" vertically in a lantern-slide, and crossing it with a similar strip of red glass fixed horizontally in the same frame. The square space where the two overlap appears absolutely black.

The same arrangement is useful for other absorption-experiments, since the original colours of the media are shown, as well as the result of their superposition.

It is necessary to remember that much lighter tints are wanted for lantern-work than for subjective experiments.

Eton College, January 10

H. G. MADAN

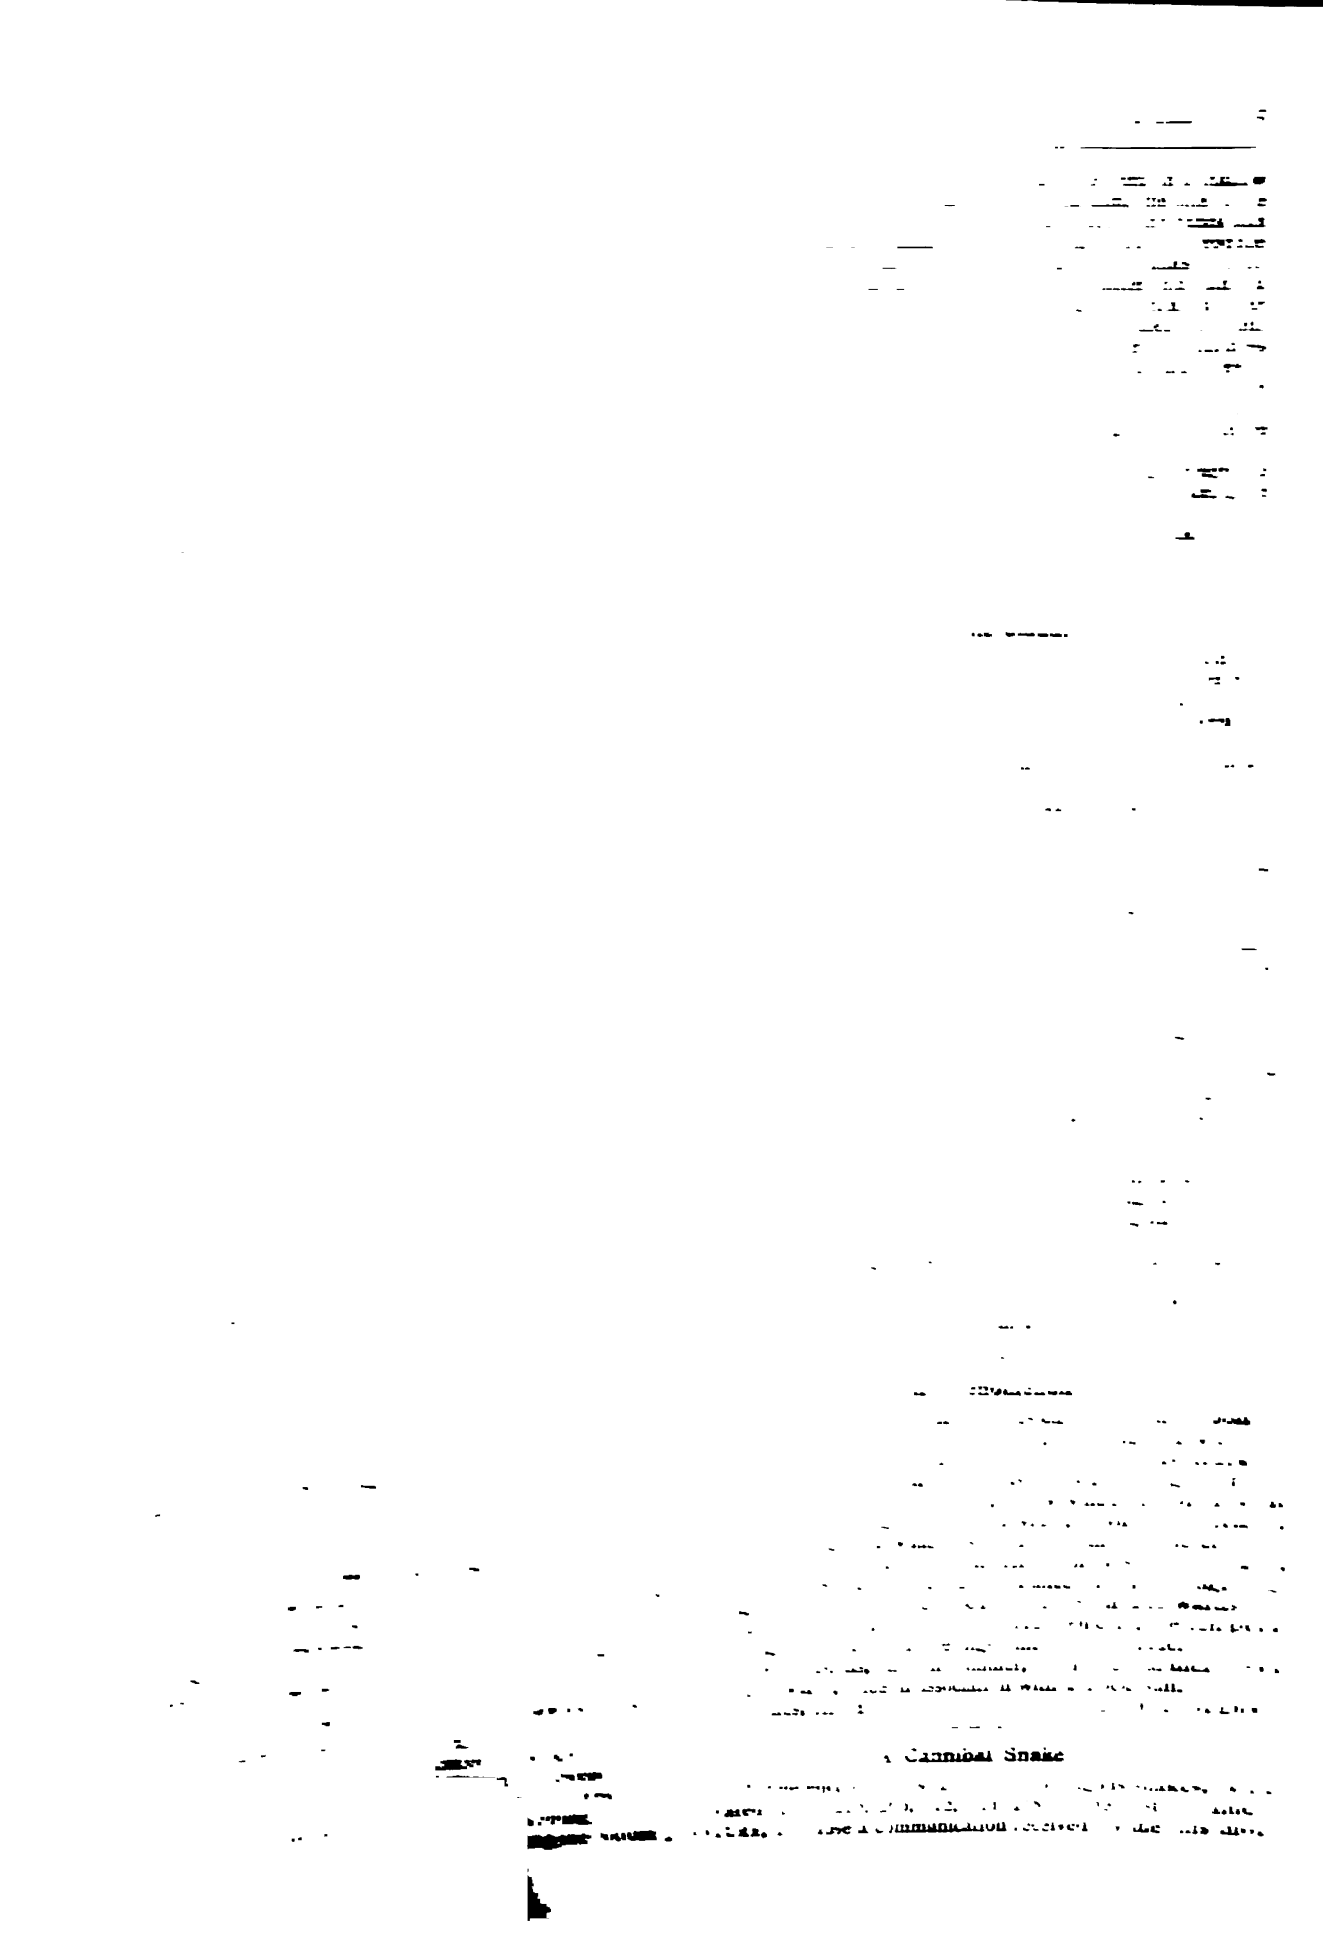
Barrenness of the Pampas

IN the admirable address of Prof. Asa Gray at Montreal, he alludes to the singular absence of trees and herbaceous plants throughout the Pampas or vast level plains of the South American continent, and he indorses the opinion of Mr. Darwin and Mr. Ball that this absence is due to the fact that the only country from which they could have been derived could not supply species adapted to the soil and climate. As this is a subject to which I paid considerable attention during a long residence in South America, I venture to call attention to the explanation of this phenomenon, which my observations gave rise to as described in my "Visit to South America," 1878.

The peculiar characteristics of these vast level plains which descend from the Andes to the great river basin in unbroken monotony, are the absence of rivers or water-storage, and the periodical occurrence of droughts, or "sicoos," in the summer months. These conditions determine the singular character both of its flora and fauna.

The soil is naturally fertile and favourable for the growth of trees, and they grow luxuriantly wherever they are protected. The Eucalyptus is covering large tracts wherever it is inclosed and willows, poplars, and the fig, surround every estancia whe fenced in.

The open plains are covered with droves of horses and cattl and overrun by numberless wild rodents, the original tenants



A Cannibal Snake

ing from Borneo. The habit seems general, and, according to the above letters, not confined to venomous or non-venomous varieties. EDWARD F. TAYLOR

St. Augustine's College, Canterbury, January 13

"*Sarawak, Borneo, November* 11, 1884

"The inclosed cutting from NATURE was sent me by H. Brooke Low, Esq., resident of Rejang, with a desire that I should forward my experience (which was similar to Mr. Evans's) to your paper. A young Dyak youth was walking up the hill towards my house, when a snake sprang out of the bank and fastened itself on the boy's jacket, just under the right arm. Fortunately, its fangs got caught in the cloth, and the boy escaped unhurt. Eventually, the reptile was killed and brought to the house. It measured five feet and some odd inches in length. In examining its fangs I noticed in its mouth the tail of another snake, and, on pulling it out and comparing them, I found it to be a few inches *longer* than the outside snake, though not quite so thick. I have come to the conclusion that this snake is the *Ophiophagus elaps* of the Straits. The native name for it is 'Ular Kendawang.' It is more deadly, more agile, and more beautifully marked than the 'Ular biliong' mentioned by Mr. Evans. So fascinatingly beautiful is the appearance of this snake, that in Dyak poetry one of their heroes is described as 'Crowned with the cast skin of the Ular Kendawang,' thus attributing to the hero that comeliness, agility, and fearlessness for which the 'Kendawang' is noted. I have reason to believe that the 'Ular biliong,' or axe snake (from the shape of its head), mentioned by Mr. Evans is an Ophiophagus, but it is not what is called the 'Elaps.' Its movements are sluggish, and its poison is not nearly so deadly as that of the 'Kendawang.' The distinctive marks of the 'Kendawang' are a reddish head and tail, the red of the tail being about twice the length of the head. The ground colour of the body is generally of a dark gray, but I have seen them of a silver gray, and also dark brown. A light streak of flesh-colour runs down the back, and the edges of it are serrated with vermilion and metallic-green spots, with just enough of white and yellow to make a most pleasing combination of colour. Besides these two, there are two other species belonging to the Ophiophagous class. The native names are 'Kengkang mas,' or 'Tinchin mas,' *i.e.* golden-ringed; and 'Matikor,' *i.e.* dead-tailed, and these four species are, I believe, very common throughout the Malay Archipelago. "M. J. BYWATER,

"S.P.G. Missionary in Sarawak"

The Canadian Geological Survey

A PHRASE used in your condensed report of my remarks after Sir J. H. Lefroy's paper, read on January 13 at the Colonial Institute, may, I fear, be misunderstood by some of my friends in Canada. I am reported speaking of the Geological Survey of that country as "being slowly conducted." My remarks were not intended to imply the slightest reproach. I explained that progress could not be rapid because of the vast extent of the territory and the natural difficulties of many parts of it. I think, indeed, that it is surprising that, having regard to the means at their disposal, the Survey have accomplished so much. I urged that, as it was impossible for the present staff to prospect specially for minerals without abandoning the general work of surveying, which is of the more importance for science, some specialist should be added to it, to whom the former duty should be assigned. I did not use quite so strong a phrase as that I "*believed* the district north of the St. Lawrence was rich in valuable minerals." My opinion is that, as certain parts are known to be rich, and as there is great uniformity in the geology of the district, it is very probable similar deposits exist in the (very large) unexplored portion. DUST[1]

MY business this evening is to talk about dust: meaning by dust all suspended foreign matter of whatever kind, and including smoke and fog under the one heading. Coming from England I should naturally begin by saying, well, we all know what dust and smoke are; and even in Canada, I suppose, I may venture to say the same, though I am bound to say that your country, at present, shows a remarkable deficiency in this respect. In an English town dust and smoke are the most noticeable features, and are always ready to perform any insanitary or other function that may be expected of them. In this clear atmosphere none of these functions can be properly performed; disease-germs must languish and die, and their sworn foes, the white corpuscles of the human blood, must thrive amain. Let me say, however, that the air here is not so absolutely free from smoke as I had hoped to find it. Compared with an English town it is a splendid contrast; compared with one's ideal it falls short. Your houses may indeed burn anthracite and wood, but your passenger locomotives do not: I can attest from very recent personal experience, in a journey across this continent, that some of your locomotives emit almost as much smoke as a Clyde steamer, and that the journey would have been much pleasanter if they had emitted less. I also see some factory chimneys rising here and there. If you be not warned in time, you will not realise the blessing of fresh and pure air until you have lost it. It is good to have large manufactures, it is better to retain healthy and pure air. But with proper care the two may go together. Once lose ground in this respect, as we have done in

[1] Evening discourse to the British Association at Montreal, on Friday August 29, 1884, by Oliver J. Lodge, Professor of Physics in University College, Liverpool

England, and terribly uphill will be the retracement of your steps. The old country has in many things made experiments for you—experiments of which you may reap the benefit, without repeating them, if you choose. The experiment of Protection, which we have tried and abandoned, I dare not here mention except just by name; but I dare mention the experiment we have tried only too successfully, and by no means yet abandoned though we groan under it—that of fouling the atmosphere, wherever a large number of human beings have to live in it, to such an extent that it is not fit to breathe. We have made a terrible mistake, and one that will take perhaps a century to undo. Tax all the necessaries of life and it is a small evil, for the tax may at any time by an Act of Parliament be removed, but pollute the air in which a people have to live and no one can see the end of the evil. You will soon have towns here rivalling Liverpool and Glasgow and Manchester in size, and some day London. Be warned in time.

However, in speaking of dust, I am not going to confine myself to such artificial dust as is made in towns, I shall include everything which Tyndall means when he calls it "the floating matter of the air," all diffused and floating foreign matter, fine or coarse. But the term "floating" is not free from possible misconception, and a better term than floating is sinking. If the two sound antagonistic, then floating was wrong. Foreign particles, whether solid or liquid, are not floating, and cannot float, in air; they are all necessarily sinking through it, and sinking at a well-defined and fairly calculable rate. Consider, for instance, the water globules of a fog, or mist, or cloud. The drops of water appear to float in air, but they are not floating, they are slowly settling down. They may in truth be buoyed up by convection currents, but they never move up *through* the air, they move up *with* the air to some extent, but are always slowly falling through it whether the air be moving or stationary. Are they then like a slowly-falling balloon or soap-bubble? No, they are not buoyed up at all—they are falling as fast as ever they can. Water is 800 times as heavy as air, and a drop of water falls under the influence of this enormous difference in weight. Why does it not fall faster? Just for the same reason as prevents an Atlantic liner from being propelled at 50 knots an hour—skin friction. A ship requires a great force to propel it at 15 knots an hour; break it up into small pieces and it will take vastly more; pound it into infinitely fine dust and it will require an infinite force to propel it at any slow pace. I do not say that a small body as it moves through a fluid experiences more resistance than a large one—it experiences less; but the decrease of resistance is not so rapid as the decrease of its bulk or weight, and consequently a small falling body is resisted more *in proportion to its weight* than a large one. Consider a bullet or a raindrop falling from a great height. As it falls it keeps moving quicker and quicker, but not without limit. Its weight remains constant, the resistance it meets with increases with its speed; hence there comes a time when the two balance and the body is in equilibrium. It then ceases to gain speed: it has attained its "terminal velocity." Even if thrown down faster than this it would slacken till it attained it. Now this terminal velocity is greater for a bullet than for a small shot, is greater for a large raindrop than for a small one, and for a mist globule is very small. The old idea concerning cloud globules, that they were hollow vesicles and therefore floated, is quite erroneous. They do not float, they sink. Slowly sinking particles, then, constitute dust, whether these particles be solid or liquid. Water dust is so important that it has various names, such as mist, fog, rain, cloud, and, in popular usage, steam.

Having now stated what dust is, the question presents itself, How did it get there? What are the sources of dust? There are certain human sources of dust—such as the traffic of towns, and the smoke of imperfect combustion. These produce coarse and heavy particles which never rise to a great height, nor float very far from their source; this dust may be regarded as mere dirt and filth. Besides this, however, a fine impalpable dust is produced by every terrestrial activity. The wind blowing through trees, the waves tossing up spray—all these natural activities disperse into the air very fine particles, which are upborne and carried so far from their source that they form quite a permanent part of the atmosphere. This fine natural dust is not limited to the lower atmospheric levels, but is almost equally abundant at great heights; to it we owe the blueness of the sky, and by it clouds and mists are rendered possible.

Another source of dust is found in volcanoes. During an eruption immense torrents of pumice and ashes are driven upwards to incredible heights, whence they slowly settle down again, the larger fragments sometimes covering the sea for acres with a thick floating deposit through which steamers slowly crunch their way, almost as if steering through land (see a graphic account in NATURE, signed Stanley M. Rendall, forwarded by Prof. Turner, vol. xxx. p. 288, July 24, 1884; see also vol. xxix. p. 375, abstract of paper by Capt. Vereker); the finer particles being carried hundreds of miles away from their source, and giving rise to brilliant appearances as they catch the solar rays—appearances recently observed over a great part of the world at sunset.

Yet another variety of dust is that which comes to us from ultra-terrestrial sources, fragments of interplanetary matter, cosmic or meteoric dust. You all know of the showers of falling stones—the August and November meteors; you know that these are lumps of interplanetary matter careering through space, mostly doubtless round the sun, but not aggregated together into planets. Cold lumps of iron they mostly seem to be, possibly fragments of some ancient world, possibly relics of the old nebulous world material, never yet aggregated into worlds at all. For ages they may have been rushing along, some almost isolated, others crowded together, and so they might rush on for millions of years; but a larger body bears down upon some of them; they feel the gravitative influence of the huge mass of a planet; they are deflected from their course notwithstanding their prodigious speed, and a few dip into its atmosphere. In an instant the terrific friction strips off their outer coat, scrapes and rubs the surface till it glows with a white heat; streams of white-hot particles are still scraped off, and form a luminous trail, but the white-hot masses plunge on: and one perhaps escapes to resume its wanderings, disturbed a little by its encounter but not destroyed; another may be rubbed to fragments altogether; another may be heated so rapidly and unequally as to explode; while another may enter the atmosphere at a more moderate velocity—may be heated indeed, and violently scraped, but not destroyed, and may embed itself in the ground, to be dug up by some peasant as a thunder-bolt and to be preserved in some museum. The frayed particles of such meteors must constitute no inconsiderable portion of terrestrial dust; and since it comes from altogether extra-terrestrial sources, it is to us of most intense interest. One other visitant from other worlds we know of, and that is light. Light is found to be charged with information, though it took man many centuries to learn how to read it—first with the telescope, now with the spectroscope, and next with who shall say what still more potent revealer and analyser of hidden truth. Meteoric dust may not be so laden with information as light is—certainly we have not yet learnt to read it. It is only within the last few years that, at the instigation of Sir William Thomson, a Committee of Section A of the British Association was appointed to consider the question whether such dust could be collected and detected at all. Under the able and energetic guidance of Dr. Schuster, this Committee has done good work, and some dust from the ice-fields of the Himalayas

and from Greenland has been definitely proved to be meteoric.

At present however no sign of organic matter or evidence of extra-terrestrial life has yet been detected in it, but any year this statement may have to be modified, and a discovery of the most intense interest may have to be announced. You have probably all heard of this theory of Sir William Thomson's, that some life germs may have been carried to the earth by a meteor, and you are probably equally well acquainted with the cheap ridicule the statement met with at the hands of newspaper article writers and the general public. It was derided as an absurd attempt to explain the origin of life. It was nothing of the kind. Nothing at all was said about the origin of life; it was a sober matter-of-fact statement that it was a scientific possibility for some organic germs or seeds to be conveyed to the earth by a meteor, to be rubbed off it at its first entrance into the atmosphere without getting overheated, and thence to slowly settle down as dust, and germinate. Well, it is a possibility, and it may before now have happened, and it may happen again, and very interesting it would be to be able to point to a case of its happening. But what then? If you account for the presence of a cherry-tree in your orchard by saying that it sprang from a cherry-stone dropped by a passing balloon, are you to be assailed as a full-blown explainer of the origin of all cherry-trees and of all forms of life?

You may take it as a fairly safe rule that when a statement is made by the highest living scientific authority, the statement may or may not be true, but it is not likely to be such abject nonsense that any newspaper article writer, in the interval between ten o'clock and midnight, can see all through it, detect its follies, and serve them up exposed for your breakfast edification.

Leaving the subject of meteoric dust now, and of the possibility of future discovery which may be wrapped up in it, let us proceed to ask, What is dust for—what purpose does it serve? We shall not enter upon the teleological inquiry, what was it intended to do; we shall simply ask what it does—a plainer, and for the most part a more instructive, question.

First, what is the function of human dust, such as is made in towns? One of its functions is to choke up the breathing organs both of plants and animals; another is to propagate disease from place to place. It is one of the most important discoveries of this century, that infectious disease is due to the growth of a specific vegetable organism in the system, propagating itself like yeast in dough, or ferments in alcoholic liquors. The germs of these organisms float about in the air from place to place, and gain positions enabling them to enter the blood of some animal organism, say man, where they can grow and flourish, provided they are able to successfully encounter their mortal foes, the white corpuscles of the blood. If these white corpuscles are strong and vigorous, they will overpower the foreign growth, and kill it. If, on the other hand, they are weak and feeble, and the germs are very numerous, the foreign growth may get a secure footing and spread luxuriantly, changing the character of the fluids of the body, coagulating, it may be, the albumen, and otherwise setting up the unnatural and abnormal display of functions which we call disease. I have only to indicate thus much to exhibit to you the enormous field of knowledge and of inquiry which is involved in the discussion of the function of dust from this point of view.

But it is not my province to discuss this, and I must hasten on to more purely physical considerations, and must ask, What is the function of the fine impalpable dust or ultra-microscopic particles in the upper regions of the air? First of all, it is this which causes the blue of the sky and the diffusedness of daylight. I have not time to go into this. I will only state it, and pass on. You will find the rudiments of it beautifully expressed by Dr. Tyndall in his Lectures on Light, but it will take Lord Rayleigh to explain it to you completely.[1]

If the atmosphere were purely gaseous, and held no minute foreign bodies in suspension, the aspect of the sky would be utterly different from what it now is. The sun would glare down directly with blinding intensity, and objects not in direct sunlight would be in almost complete shadow. A room facing north would be in something like darkness: at least, it would be only illuminated by reflection from illuminated objects outside. The sun would be set in a black firmament, and if its direct light were screened off it would be easy to see the stars at noonday. (Through dust-free air light passes on without loss by scattering, and is quite invisible except to any eye placed directly in its course. [Tyndall's optically empty tube was here shown.] There is nothing remarkable in seeing nothing, when no dust or other reflecting body is present. When you see motes dancing in a sunbeam, it is not the motes which render the sunbeam visible. but the sunbeam the motes; and of course light is invisible which does not enter the eye.)

What is the actual state of things as contrasted with this? The sun's rays on reaching our atmosphere are partially intercepted, diffused, and scattered by myriads of most minute particles, so minute as to be even smaller than the light-waves themselves, and to act on the smallest of these waves more powerfully than on the largest. The light thus scattered is the diffuse daylight so entirely satisfactory and pleasant to the eye, and so inimitable by artificial systems of illumination. The light thus scattered has a preponderance of small waves, owing to the minute size of the scattering particles, and hence it affects our sight organ with the sensation of blue. By this scattered light shadows are mellowed, the intensity of direct sunlight is mitigated, and the whole expanse of sky glows with a perfect lustre, effectually drowning the light from the more distant celestial bodies. Above the top of a high mountain dust is almost absent, and there the sky has been observed at times to look almost black, and stars are sometimes visible in sunlight.

But besides the blue of the sky, we owe to this dust the possibility of clouds, which still further intercept and scatter the solar beams. "Cloud is visible vapour of water floating at a certain height in the air," says Mr. Ruskin[2]; but he is not quite right in his language. True vapour of water is invisible, and that which is visible is no longer vapour, but condensed vapour. It is vapour which has condensed to liquid—not to great masses of liquid, but to minute globules or spherules of liquid, so small as only to sink very slowly through the air. What makes the vapour condense into this water-dust form? Why does it not condense at once into great masses or sheets of water? Something there must be to start the condensation at multitudes of separate points, so that the vapour shall condense the instant it is saturated, without ever becoming supersaturated. Things that act in this way are called nuclei. Without a nucleus, it is as easy for a phenomenon to begin at one place as at another, and when that is the case it does not begin anywhere: there is no preponderating cause. Wherever there is a nucleus, however, there the action can begin; and in order that action may commence at an infinity of points at once, it is necessary that an infinity of nuclei exist. The action of nuclei is readily illustrated by the well-known experiment of a supersaturated solution of Glauber's salts. The solution remains liquid until a nucleus is introduced, when it becomes suddenly converted into a solid. (I don't say that it is clear *why* nuclei are able to start the action. What is there at the surface of discontinuity to make change of state easier there than anywhere else? It will take a bigger man than me to tell you that.[3])

[1] *Phil. Mag.*, August 1881. [2] "Storm Cloud" lecture, p. 12.

[3] Sir W. Thomson has partially indicated a reason for it in his theory the effect of curvature of surface on vapour-tension. See Maxwell's "H chap. xx. p. 268.

Now this sudden conversion is just what might happen in the case of the atmosphere, only the change of state would be from vapour to liquid. Picture to yourselves aqueous vapour accumulating and increasing in quantity in dust-free air, saturated, over-saturated, nothing to start the condensation; it goes on accumulating; the atmosphere becomes unbearably damp, soaking into and through everything. At length at some point something causes it to give way, and condensation takes place. Instantly it spreads from this point as from a centre, volumes of liquid are produced, and fall not as a shower but as a splash, deadly and destructive by the mere weight and impetus of its fall.

Instead of this, what really happens? The moisture, on becoming saturated, finds myriads of minute dust particles or nuclei, round which it condenses; the more numerous the nuclei, the more minute may be the globules of mist formed; it never becomes supersaturated at all. The instant it is saturated it begins to condense, and we have the mist or visible cloud, and in this form it may last for any length of time. Under certain influences, however, not yet fully understood, but which I wish in part to illustrate to-day, these minute globules may congregate into larger ones. Too large to remain slowly falling through the air, they begin to fall more quickly as their size increases, and we get the fine shower; or, if the aggregation goes on further, and the drops do not evaporate much as they fall, we have the heavy downpour, the thunderstorm, or the tropical deluge—all varieties of rainfall caused by the different size of the aggregated water globules.

Were there no nuclei, condensation would not begin, and were there but few nuclei, condensation could only begin at a few points, and a quite different kind of mist might present itself; one which would consist of comparatively large and rapidly sinking globules—small for raindrops, but large for mist globules, a kind intermediate between mist and rain, such a mist as is met with in clear moist climates, and known in England as a Scotch mist.

Note this, that to get a fine permanent fog, you must have an enormous number of centres of condensation. Mr. Aitken (*Trans. Roy. Soc. Edin.*, about 1879) established this fact, that every spherule of mist must have condensed itself round a minute solid dust particle, a nucleus, and that without such nuclei condensation could not go on. The minuteness of the nuclei able to act in this way is extreme, an almost immeasurably small quantity of matter being sufficient to precipitate a copious cloud. Their size is quite beyond a microscope.

[Mr. Aitken's experiment was here shown with apparatus from the Royal Institution. A long glass tube is filled with moist air, carefully filtered through cotton wool and glycerine, after Tyndall, and is then suddenly exhausted by an air-pump. It is thus cooled far below the dew point, but no precipitation occurs; and the tube, well illuminated, is seen to remain clear. Now ignite a platinum wire inside it with a few Grove cells, and let more filtered air enter. As soon as this is done exhaust again; instantly a thick cloud is precipitated, condensation occurring round myriads of nuclei given off from the platinum wire—which, however, has not appreciably lost weight. I wonder if this experiment could not give Sir Wm. Thomson a fifth limit to the size of atoms by estimating the loss of weight of the platinum spiral and the number of globules in the resulting mist.]

A familar illustration of the effect of nuclei on vapour is given by the simple experiment of writing on a pane of glass with a stick, and then breathing on it. Where the writing has wiped away the dust, the moisture condenses less easily and in much fewer and larger globules than where nuclei are abundant; consequently the writing becomes visible.

In studying the properties of any physical agent, it is essential to be able to employ it or exclude it at pleasure. One must have insulators to investigate electricity; one must perform optical experiments in a dark room; and to study the properties and functions of dust it is important to be able to remove it, and to obtain dust-free spaces.

Methods of removing dust from air are:—

(1) Filtration through cotton-wool, or cotton-wool and glycerine, packed tightly. Tyndall has shown how effective this can be made with proper management.

(2) Allowing it to settle. In a few days or a week most of the dust has settled out of stagnant air. Prof. Noel Hartley employed atmospheres of hydrogen in his old and careful experiments on "spontaneous generation," because it was too rare for germs to float in.

(3) Condensing vapour in the air several times. Mr. Aitken has shown that successive condensations of vapour gradually purify air by removal of nuclei, until it is quite clear. He shows that the ability of vapour to condense is an extremely delicate test of the presence of such nuclei, and that when the dust particles are very few, condensation takes place not as cloud but as fine rain or Scotch mist. Doubtless, the cause of actual Scotch mist is the clearness and purity of the Highland air induced by frequent and continued rains.

(4) Keeping a hot body in air for some time. This, Tyndall calls "calcining" the air.

(5) Discharging electricity into it from a point.

I must say a few words about the two last methods. When a hot body is held under a sunbeam, a dark stream of dust-free air is seen rising above it. This was discovered by Dr. Tyndall, and investigated by Lord Rayleigh, as well as by Mr. Clark and myself.[1] A hot spiral of platinum wire in a bell-jar produces this dust-free stream, and so gradually clarifies the air in the jar. That this is not due to combustion or evaporation we proved by using the smoke of burnt magnesium, which answers perfectly. Lord Rayleigh has shown that a cold body is similarly effective, and causes a *descending* dust-free stream.

We have found that the dust-free streamer is only a prolongation of a dust-free *coat* which surrounds all warm bodies. The dust is kept away from them by molecular bombardment. It has been shown by Tait and Dewar, and by Osborne Reynolds, that a Crookes bombardment is effective at even ordinary pressures provided the bodies bombarded are small. Dust particles are very small, and so they get driven by molecular impact away from hot surfaces and towards cold ones: the distance through which they are so driven away being easily measured by observing the thickness of the dust-free coat round an illuminated body at known temperature.[2] Two black tin vessels or glass flasks can be put under a bell-jar, one of the flasks full of warm water, the other of cold. On now burning magnesium, or otherwise filling the jar with smoke, the cold one will presently be found thickly covered with a deposit, the warm one will be nearly free. What Tyndall calls "calcining" the air, then, is really bombarding the dust out of it on to the cool wall surfaces. The deposition of lamp-black on a cold body held in a flame is thus explained. Whenever the air is warmer than bodies it deposits its dust and smoke upon them; whenever bodies are warmer than the air they keep the dust off, except when the weight of some of the larger particles is sufficient to overcome the bombardment; a thing which is very likely to happen on a horizontal and slightly warm surface.

[1] Mr. Aitken commenced the same investigation after reading my preliminary note of July 1883 in NATURE, and has followed it up in much the same way as we have, obtaining very similar results. I have just seen Mr. Aitken's paper in the *Trans. Roy. Soc. Edin.*, vol. xxxii. Part II. He therein criticises one or two of the views I somewhat hastily expressed in the preliminary note referred to. But our views were naturally modified by further experience, and in the complete paper in the *Phil. Mag.*, March 1884, they are more carefully expressed. It would have been better if I had not written to NATURE until the investigation was complete.

[2] See Lodge and Clark, *Phil. Mag.*, March 1884; also NATURE, July 26, 1883, vol. xxviii. p. 297, and April 24, 1884, vol. xxix. p. 612.

nuisance. Electric light is powerless to penetrate it; and it was impossible, as we lay there idle, not to be struck with the advisability of dissipating it. It is rash to predict what can be done, it is still rasher to predict what can not. I would merely point out that on board a steamer are donkey-engines, and that these engines can drive a very powerful Holtz or Wimshurst machine, one pole of which may be led to points on the masts. When electricity is discharged into fog on a small scale, it coagulates into globules and falls as rain—perhaps it will on a large scale too. Oil stills the ripples of a pond, and it has an effect on ocean billows; just so an electric discharge, which certainly coagulates and precipitates smoke or steam in a bell-jar, may possibly have an effect on an Atlantic fog. I am not too sanguine, but it would not cost much to try, and even if it only kept a fairly clear space near the ship, it would be useful. There are other possible applications of this electrical clearing or deposition of dust, but I am not here to talk of practical applications but of science itself. A homely proverb may be paraphrased into a useful motto for young investigators. Stick to the pure science and the applications will take care of themselves. I am not one to decry the applications of science for the benefit of mankind, far from it, but while the rewards of industrial applications are obvious and material, and such as will always secure an adequate following, the rewards of the pursuit of science for its own sake are transcendental and immaterial, and not to be imagined except by the few called to the work. That call entails labour and self-sacrifice beyond most other, but they who receive it will neglect it at their peril.

HEREDITARY DEAFNESS[1]

THE startling title of Mr. Graham Bell's admirable memoir is fully justified by its contents. It appears that there are upwards of 33,000 deaf mutes in America, mostly collected in large institutions forming social worlds of their own, whose inmates intermarry or else contract marriages with the hearing relatives of their fellow pupils, who themselves, in many cases, must have an hereditary though latent tendency to deafness. This state of things has been going on increasingly for two or more generations, with the result that congenital deafness, which in other countries appears sporadically, and mostly fails to obtain an hereditary footing, has become artificially preserved in America, and is intensified by inter-marriages, until a deaf variety of the human race may be said to be established. There can be no question, after reading the mass of evidence submitted by Mr. Graham Bell, of the general truth of this summary statement. That precise knowledge that we should be glad to possess, of the strength and peculiarity of the hereditary taint, is unfortunately unattainable owing to the imperfection of the records kept at the institutions of the after history of their pupils; but the data, such as they are, have been handled with great statistical skill by the author, so that he has squeezed all the information out of them that they appear competent to give.

We may now go a little more into details. It appears that out of six asylums, with an aggregate of 5823 pupils, 29·5 per cent. have deaf relatives. Also that nearly half the pupils contract marriages, and that 80 per cent. of those who do so, marry together. This ratio of inter-marriage is much greater than it was at the beginning of the century, and it appears to have steadily increased from then up to the present time. It is unfortunate that the imperfection of the records kept at the institutions make it difficult to ascertain the exact rate of the increase or the precise fate of the issue of all the marriages. This latter fact may, however, be estimated by working back-

[1] "Upon the Formation of a Deaf Variety of the Human Race," by Alexander Graham Bell, National Academy of Sciences, New Haven, U.S.A., November 13, 1883.

wards, and finding the number of deaf-mutes known to exist among the ancestors of the present inmates of the asylums. The family history of many of these is appalling, such as "Grandfather, father, mother, and other relatives"; "father, mother, one brother, and five uncles and aunts"; two cases of "father, mother, one sister, one uncle, and one aunt"; two cases of "father, mother, two brothers, and two uncles," and so on. In one case as many as fifteen deaf-mute relatives are recorded. Genealogical trees are given of the families in which deaf-mutism prevails, and the large proportion of the members of those families who are congenitally afflicted is most painfully illustrated. The surnames of the inmates of deaf-mute asylums are analysed, and the frequency is pointed out of the recurrence of many strange-sounding names, such as "Fahy," "Hulett," "Closson," "Brasher," "Copher," "Gortschalg," &c., apparently out of all proportion to the number of persons bearing those names in the general population.

The influences that promote the inter-marriage of deaf-mutes are fully described. The isolation of their class from the rest of the world is becoming more and more complete. Each institution is a self-sufficing *alma mater* where every member feels really at home, and with which each member continues his connection in after years. Gatherings of old pupils of both sexes, *conversaziones*, and other social meetings are of frequent recurrence, and what is most important of all, the highly-developed and very conventional gesture language of the deaf and dumb has already moulded them into a distinct nation. They think not in words, but in abbreviated symbolic gestures, and the sequence and association of their ideas is thus compelled to be idiomatic and widely different from those of the rest of their race. English and other spoken languages are foreign tongues to them, and are acquired, for the most part, very imperfectly. A separate mode of life is so congenial to persons reared under such exceptional surroundings, and of such exceptional natures, that unwise schemes have been from time to proposed, of buying land in settlements for the deaf and dumb, where they should reside and form a secluded society of their own. They are content with their lot when they are brought into contact with none but themselves, but they are ill at ease, and feel themselves to be aliens, when they are forced into the presence of the outside world. What wonder that they should shrink from it, and intermarry and strive to keep apart.

The interest of this strange story is twofold. In the first place it shows how easily a marked and degenerate variety of mankind may be established in permanence by a system of selection extending through two or three generations; and, secondly, it is an instance in which strong social, and possibly legislative, agencies are sure to become aroused against unions that are likely to have hereditary effects harmful to the nation. The advisability of various forms of restrictive measures is judiciously and carefully discussed by the author, with the general result that gesture-language should cease to be taught, the oral system being enforced in its place, and that the philanthropic custom of massing the deaf and dumb together in separate societies, and of making their life as happy as possible in those societies, should be strongly discouraged.

Instructive experiments on the rate at which a deaf breed of animals could be formed, might be made by breeding deaf cats, who are by no means inefficient mousers, and who show no signs of discontent at their lot. I may mention an observation of my own as having some possible pathological bearings. It was this: during a country walk I lunched at a roadside inn, where I saw a female cat with blue eyes, and asked and found that she was quite deaf, but was told that her kittens all heard perfectly. The only one of them that had been kept was in the room, and she certainly noticed my voice and other noises I made to attract her attention, just as readily as other kittens. Then it occurred to me to try her with the shrill notes of one of my little whistles, which I had in my pocket-book. She was absolutely deaf to these, and I doubt if she could have heard a note as shrill even as the chirp of a sparrow. Cats, as I have elsewhere observed, are eminently sensitive to shrill notes, so that the deafness of this kitten was a noteworthy proof that the imperfect stages of the form of hereditary deafness to which she was subject consisted in the degeneration of that part of the auditory apparatus which is concerned in hearing shrill notes. I am told that no thorough anatomical investigation has yet been made into these matters, owing to insufficiency of subjects. It would therefore seem that a breed of deaf cats might be very acceptable to physiologists, and I have no doubt that such a breed might be easily established on any small and sparsely-inhabited island from which every hearing cat had been removed. Cats will not breed in strict confinement, and their roving habits at night make it impossible, under ordinary circumstances, to keep their breed pure; but in small islands, under the paternal despotism of a popular landlord, this and many analogous experiments in breeding varieties of small and hardy animals and plants, such, I mean, as would take care of themselves, might be carried out. I have often envied the facilities afforded to such projects by the geographical and social condition of the Scilly Islands.

FRANCIS GALTON

ASTRONOMICAL TELESCOPES FOR PHOTOGRAPHY[1]

II.

THE simplest form of the reflecting telescope is that in which only one reflecting surface is used, known as the Herschelian, or, as Sir John Herschel, in his work, "The Telescope," calls it, "the Simple Reflector." The remarks he makes on this form are well worth most careful consideration in connection with the use of the reflecting telescope for photography.

All other forms have the second or third mirror only for the purpose of bringing the image formed by the large mirror where it can be more conveniently used. Of these the Newtonian is the simplest and perhaps the best, as here the second reflection does not alter the size of the image, but only diverts it to the side of the tube. In the Cassegrain or Gregorian form the use of the convex or concave mirror enlarges the primary image more or less. Modifications of the Cassegrain form can be made by replacing the small convex mirror by a flat or very slightly curved mirror, in which case, although there is much loss of light, the image is kept nearly the same size as in the Newtonian. There is also the "Brachy" form, where the Cassegrain is used obliquely, but this is practically a Cassegrain. In all these telescopes, except the first and last-mentioned, the second mirror requires support of a kind that acts most injuriously on the image, causing rays to come from stars which, in the case of stars as faint as eight magnitude, show quite distinctly with such long exposures as are needed in photographing the nebulæ or clusters of very faint stars. In addition to these well-known forms of the reflecting telescope there is the arrangement of three reflectors as a telescope indicated by me in the May number of the *Monthly Notices* of the Royal Astronomical Society, and also the application of the Coudé principle, treated of at length by M. Loewy in the June number of the *Bulletin Astronomique* (1884). As far as I know there has not been any practical application of the Coudé principle to the reflector. The need of three reflections would involve great loss of light, and for this reason alone would render it unsuitable for photo-

[1] Continued from p. 40.

graphy where so much depends on the power of the telescope to bring together as much light as possible on the surface of the sensitive plate. Apart from this great loss of light there would be enormous difficulties in making such a telescope of even three-foot aperture, indeed, I am very doubtful if it could be done, there is the difficulty of keeping the different mirrors free from flexure and in proper adjustment, there is the fact that the form of mounting that must be used to carry the ponderous mirrors would be that most unfavourable to the good performance of the whole as a telescope in regard to the atmospheric disturbance due to the mounting; and last, though not least, the position of the external plane mirror would be so exposed that it would not stand many nights' work; with the flat mirrors of a Newtonian telescope one has much difficulty, as a slight rise in temperature will dew them at once, and under ordinary circumstances they become very soon so dull that they require re-silvering many times more frequently than the large mirror. Certainly the large plane mirror would conserve its heat better than the small flat of a Newtonian, but from the exposed position it would occupy, it would certainly be a source of continual trouble. There is only one good thing in such arrangements, and that is that the observer has not to follow the eye-piece, which only rotates, and does not change its position. For general observational work this becomes of importance. For comet-seeking, for which I believe this telescope was first used, it is difficult to imagine a more suitable arrangement than that brought again to the notice of astronomers by M. Hermite in *L'Astronomie*, October 1884, though his proposition, to dispense with a tube or to use a fixed one, would make a difficulty at the eye-end, where the image would rotate, as it would in the case of a fixed telescope with a mirror moving in front, after the manner of a siderostat. For photography all those latter forms of telescope are not admissible; even for large fields, when a refractor specially made was used, it would be better to use it as a simple equatorial than to lose the light by two additional reflections. Considering carefully the different reflecting telescopes enumerated above, there does not appear to be anything that can be more simple than the Herschelian, and nothing more suitable, judging from what has been done, than the Newtonian; nor does there seem anything in any other form that offers greater advantages than these, either on the grounds of simplicity, easy manipulation, possible increase of size, and, what is of vital importance, smallness of first cost; it is on one or the other that I should entirely rely as the photographic telescope of the future; whether the Herschelian form would be better in practical use than the Newtonian, or, rather, whether the reflecting surface could be made as good in this case, would only be shown by actual trial; if it could then, for the reason already mentioned, the image would be the best, and the best kind of telescope for the purpose of photography would be found.

In the Newtonian, as has been said, the plane mirror is only used to bring the rays, that would form the image otherwise in the centre of the tube, out at the side, but as the object is not to be viewed, but photographed, the plate can be placed in the proper place to receive those images direct from the large mirror, as was done by Dr. De la Rue when he first used the reflecting telescope for photographs of the moon.

There are some difficulties in getting a proper supervision of the exposure, but these are not insuperable. A mounting for the Newtonian reflector pure and simple would be equally suitable for the Herschelian, so that if it were decided to make a large telescope, no danger would be run that success would not be certain; if the Herschelian gave such excellent results, as I think might be fairly expected, so much the better, if it did not, the telescope that has already shown its capacity would simply remain what it is now—the only telescope suitable for photography on such a scale as can be really useful.

As to the way in which such a telescope as I here contemplate, that is, a reflector of from 5 to 8 feet aperture, should be mounted, there would be a certain safety in following the plan I have found so good with 3 foot, with such mechanical alterations as the use of water in place of mercury for the floating medium would render necessary. The general principles, I believe, are correct as regards the conditions that affect the performance of the telescope as an optical instrument.

The duty of the observer would now be entirely limited to seeing that the image fell always on the same place on the plate during exposure, a duty that is easily described, but not so easily done. For this purpose he must have such optical arrangements that he can from the ground watch the position of the image of a star anywhere near the object to be photographed in its relation to a cross wire attached to and moving with the sensitive plate, so that if, from the many causes that can produce a shift of this star and of the image on the plate, there is a slight movement, he can at once correct it. The telescope would work entirely in the open air under the most favourable conditions and without any disturbance from the body of the observer, as he would not be near the high end of tube. The large mirror would be protected from dew by a slight covering round the skeleton tube, and have an apparatus to cover it up quickly, and so be in the best condition to keep its polish, and with the absence of a small mirror and its trouble at the high end of the tube, simplicity would be followed to its fullest extent without the sacrifice of one essential point.

Such a telescope would be capable of giving photographs of all the nebulæ, with exposures of from 30 to 60 minutes, of the various clusters, and of certain selected parts of the heavens, and this should be for some years its chief work. About the value of such a work it is quite unnecessary to speak—to show that it can be done is quite enough.

In thus giving my opinion as to the best kind of telescope to use for this most important part of astronomical photography I place it first for its importance. That much could be done by a smaller instrument, or, rather, by many smaller instruments, of a most valuable character, I have not any doubt. It is quite possible now, by means of photographic lenses, to take stellar photographs that are of great value; and any equatorial reflector, and many refractors, if they have driving apparatus of fair quality, could be most usefully employed in photography, and that without any more knowledge of the art of photography than could be learnt in a few minutes; by taking photographs of a small portion of the sky that could be identified, and working entirely at that, the amateur astronomer, with any aperture over 6 or 8 inches, could make a monograph that would be good for all time, and his results would not be the mere expressions of impressions on his mind through his eye, but would be visible ones that would speak for themselves as to their value. In all departments of stellar photography, excepting of course absolute positions, I think that photography is at once available. It is remarkable that the silver-on-glass reflector has proved itself to be capable of practically unlimited increase in size and to be so well fitted for photography at the same time that the photographic process has been brought to such a state of perfection, especially in this country, the home, if not the birthplace, of the reflector. At the present moment a gigantic stride in advance is to be made with certainty of success, and that at a cost that is insignificant compared to the results that must come. Let us hope some one who can hasten this step will come forward; if one cannot, many must, for should not be delayed.

A. AINSLIE COMMON

SOME EXPERIMENTS ON FLAME

IN December 1881 my attention was casually called to the popular superstition that sunlight puts the fire out. Returning from a walk I had found the blinds of my sitting-room closely drawn, for the benefit, as I was told, of the fire, which was low. On my appearing somewhat sceptical about the use of this proceeding, my landlady cited the above-mentioned superstition as a well known fact. For her benefit and instruction I made the poker red hot, and focused the sun's rays on it with a bull's-eye, showing her that, though the bright light prevented the red heat from being seen, it had not extinguished it, and was, moreover, capable of making a smaller piece of metal red hot. But I was myself so struck with the power of even the December sun in overcoming the light of the most highly incandescent body, that I determined to make further experiments. Even the intense glow produced by heating in the blowpipe flame a small piece of chalk, though it was sufficient to light up the whole room, entirely disappeared in the sun's rays. This led me to ask what would be the result of testing the sun's light in the same way against that of a flame. If, according to the older theory, luminous flame consists of incandescent solid particles, then I should expect that these would behave under the strong light exactly as the white-hot iron did, while, on the other hand, if as some have maintained the white light of a flame proceeds from gases of great vapour-density, then I might expect results which, if not different, would be at least interesting.

Experiment 1.—Accordingly, on December 7, 1881, I arranged my large condenser—a lens 5 inches in diameter, and 20 inches focus—so as to throw the image of the sun upon the flame of a paraffin candle. To my delight a round spot of light of a bluish-white colour and peculiar soft appearance was visible on the flame itself. That the flame, whether gaseous or consisting of incandescent particles, could reflect light, was certain. It remained for me to determine the characteristics of this reflection. From its colour and peculiarly "soft" appearance it reminded me of fluorescence. I therefore proceeded to test the question with the spectroscope.

Experiment 2.—I examined first the spectra given when a beaker of petroleum or one of solution of quinine sulphate was placed in the focus. I should mention that my spectroscope, which I designed and made myself, slides up and down the supporting pillar, so that it can be adjusted to any height. The table carrying the slit, and telescope, and prism (dense flint of 60°), can be fixed in three positions to the stand, so that the slit may be vertical, horizontal, or directed vertically downwards for examining solutions with the light thrown up from beneath. It is also provided with a doublet, equivalent to the B eye-piece of a microscope, used as a condenser to throw the image, which may be an enlarged or diminished one at pleasure, of any object upon the slit. The whole arrangement is very simple, and far more convenient than that of the ordinary laboratory spectroscope. Bringing the instrument thus armed to bear upon the strongly illuminated solution, I found the field of view to be filled with a soft and even light, that seemed to obscure the Frauenhofer lines as if some thickened luminous solution had been poured over them. Every moment some particle of dust floating into the focus would cause a tiny flash as its image crossed the slit, of hard clear light, like that of the candle-flame, only that it showed the Frauenhofer lines. But after filtering the solution, carefully cleaning the beaker, and excluding all extraneous light, the Frauenhofer lines vanished, and nothing was visible either with quinine or petroleum but the soft continuous spectrum of fluorescence. I have described these well-known phenomena thus minutely that I may emphasise the very different results obtained in the following experiment. To the naked eye the spot of sunlight upon the candle-flame was of exactly the same soft quality, and nearly the same colour as that upon the fluorescent solution. I replaced the candle in the focus, arranged the condenser of the spectroscope so that the white spot should come upon the centre of the slit, and occupy one third of it. The field of view was filled by the spectrum of the flame, but across the centre was a bright band of light extending far into the violet, brightest in the blue and showing *all the Frauenhofer lines distinctly*, especially in the blue and violet. Unmistakably I was dealing with reflected light, and not with fluorescence. My thoughts at once reverted to Prof. Tyndall's "blue cloud." I knew of two ways of producing an extremely fine precipitate showing the same characteristic phenomena. I added dilute hydrochloric acid to a weak solution of sodium hyposulphite, but this preparation I found to be troublesome from the rapidity with which it loses its optical properties, so I discarded it in favour of the following. I diluted some French polish with about fifty times its bulk of methylated spirit, and added a few drops of the solution

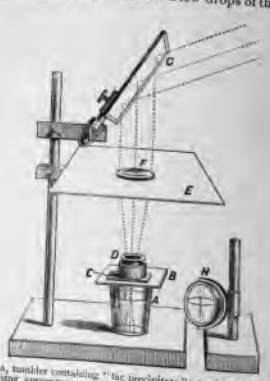

FIG. 1.—A, tumbler containing "lac precipitate"; B, glass plate to support polarising apparatus; C, selenite film; D, polarising prism; E, sheet of cardboard to screen off superfluous light; F, lens to concentrate the light; G, mirror; H, side mirror in which the colour of the beam in a different azimuth may be seen.

to a glass of water. The precipitate of lac resulting is sufficiently fine for every purpose, and will remain in suspension for days. The light from the heliostat passing through this solution gives the same soft opalescent reflection, with the same spectrum strongest in the blue and violet, showing all the Frauenhofer lines distinctly, as it does upon the candle-flame.

Experiment 3.—There is another special characteristic of matter in extremely fine division common to Prof. Tyndall's "blue cloud" and the above-mentioned solutions. Light reflected from it is completely polarised in the plane at right angles to the line of incidence. I am in the habit of showing this by the following arrangement, which I believe to be new, and which is so simple that any one can exhibit it. It is shown in Fig. 1. A is an ordinary plain tumbler, half filled with "lac precipitate," and covered with a piece of window-glass, B. On B is laid a mounted selenite film, C, and upon this again the polarising prism D, used with the microscope. A retort-stand supports a sheet of cardboard, E, with a hole in the centre, which shades the

and also carries a lens, F, which may be an ordinary eye-glass laid across the hole, and so adjusted that its focus shall come about the middle of the liquid. A plane mirror, G—a hand-glass will do—is then either held or fixed, so as to reflect sunlight perpendicularly upon the lens. It will readily be seen that the light, concentrated by the lens, is plane-polarised by the Nicol prism, then modified by the selenite, and finally analysed by reflection from the extremely minute particles of lac. Accordingly, to a person walking round the table with his eye on a level with the tumbler, the vertical beam of light in the liquid appears to change colour four times. Thus, if the selenite and Nicol are so adjusted that viewed from the west it appears blue, then from the south it will be yellow, from the east blue, and from the north yellow again. If then the selenite be removed from under the Nicol, from both west and east it will be seen as a bluish-white beam of light, while from the north and south it will be invisible altogether, as though a screen had been placed over the lens. By arranging or holding a small mirror, H, at an angle of 45°, by the side of the tumbler, the observer may see the blue colour of the beam from the west side, on which he stands, while at the same time the mirror shows him that its colour, when viewed from the north or south, is yellow. Or three mirrors may be arranged so that all four aspects of the beam may be observed at once. I do not know a more beautiful and striking way of demonstrating the properties of the polarised ray.

Experiment 4.—I now come to the most interesting of my experiments. This polarisation of all light reflected at right angles to the line of incidence is, I believe, accepted as the special characteristic of very finely-divided solid matter. I applied the test to the light upon the candle-flame. I held the Nicol in the plane at right angles to the mean path of the rays, looked through it at the soft spot of reflected sunlight, and rotated it. When the crystal crossed the line of incidence at right angles, the spot vanished; when it coincided with it, the spot was brightest. With a selenite film in addition to the Nicol prism the usual change of colour could be seen, the red and green film showing more distinctly than the blue and yellow. By using the Nicol over the eye-piece of the spectroscope I found that every part of the spectrum of the reflected sunlight is polarised alike, showing that the flame behaves with respect to light exactly as a solution containing extremely fine solid particles. I made a large number of experiments with a view to ascertain how far this similarity would hold, and I now proceed to give some of the most important.

Experiment 5.—I arranged the heliostat with the candle-flame in the focus and the spectroscope at right angles to the line of incidence, with the Nicol prism over the eye-piece, and the condenser arranged to focus the "white spot" of sunlight on the slit. I then gradually lowered the candle so as to bring the apex of the flame into the light. There was no break in the appearance of the spectrum on passing from the hot flame to the non-luminous smoke. Low down, the flame reflected only the more refrangible rays, as far as the middle of the green; towards the apex it reflected also the red. All the reflected light was polarised.

Experiment 6.—With the same arrangement as before, I turned the spectroscope so as to have the slit horizontal. I burnt some soda in the Bunsen burner at a little distance, so that the vapour from it came to the candle. The result is depicted in Fig. 2. The continuous spectrum of the inner flame is crossed by the bright sodium lines which project a little distance beyond it on either side to the limits of the outer flame. In the centre is a bright band, the spectrum of the sunlight on the flame, and on this all the Frauenhofer lines, *including the D lines perfectly black*, as in my drawing. It was very curious to see the two ends of the sodium lines standing out bright against the dark background on either side, visible still as bright lines, though faintly, upon the flame itself, up to the band of sunlight, and then strongly reversed by contrast with its greater brilliancy. I believe I am the first who has succeeded in reversing the sodium lines by reflection. It requires a bright sun to do this; otherwise the red end of the spectrum is not strong enough, but I have succeeded in showing it to several friends.

Experiment 7.—With the same arrangement, substituting a spirit-lamp charged with soda for the candle, nothing was visible to the naked eye; the flame seemed

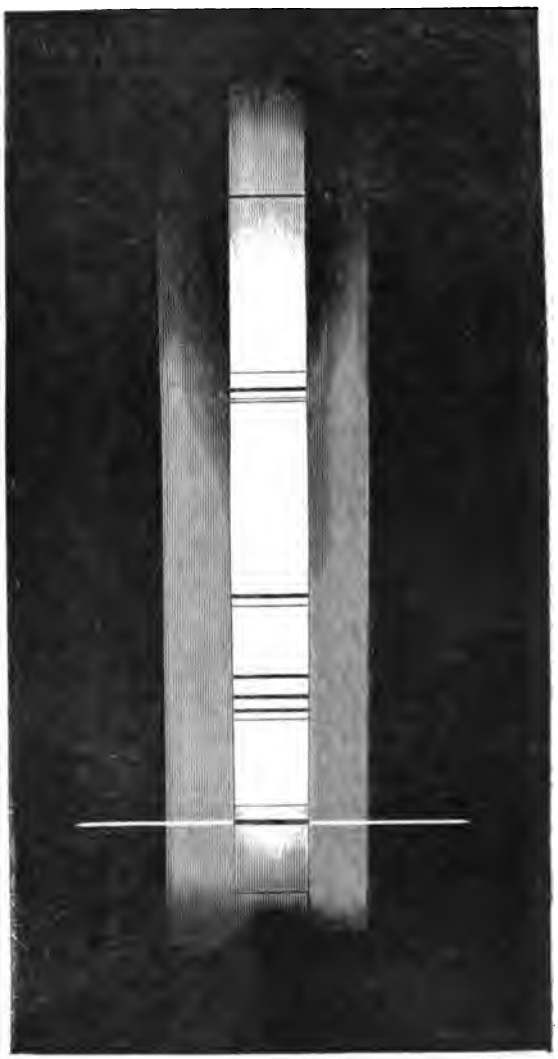

FIG. 2.—Spectrum of candle-flame in the focus of the heliostat, showing the D lines reversed by reflection.

to vanish in the glare; only in the spectroscope the bright lines were seen unaltered. With the Bunsen a brightly illuminated column of dust was seen rushing out of the tube, each particle vanishing as it reached the perfectly invisible flame, and was burnt. Several substances, *e.g.* copper oxide, and ammonium molybdate give in the outer flame a spectrum which in my small strument appears continuous, though lacking the "har look of the spectrum of an incandescent solid. But th give *no reflection* with the strongest sunlight, behaving true vapours. It will be observed that, though I ha

shown that a substance capable of emitting light of *all* wave-lengths may be capable of reflecting at the same time light of *any* wave-length, yet I have not been able to show whether or not a substance emitting light of one definite wave-length may not be able to reflect light of that same wave-length, though I have proved that it can reflect no other. For instance, the light given by sodium is absent from that of the sun, so that my experiment proves nothing with regard to it; yet that particular light is not transmitted through hot sodium vapour, but is stopped by it. One would think it must either be reflected or its energy must be used up in some way on the vapour itself. I have been unable to get access to the electric light, and no other light I know is strong enough for this experiment. I have wished also to try whether sodium burnt under pressure, or at a very high temperature, would or would not have the power of reflecting light; but in this direction I am again stopped by lack of apparatus.

Experiment 8.—The spectrum of the light transmitted through the lac solution is complementary to that reflected by it, *i.e.* the reflected light is bluish, and the transmitted yellowish-brown; in the latter case the spectrum is weakened towards the violet, and in the former towards the red. I desired to see if this was so with flame. I arranged a metallic screen with a slit one-fourth of an inch long and one-twentieth wide, close to the candle, so that all light falling upon the spectroscope must first have passed through the luminous portion of the flame, and then with a mirror directed the sunlight into the instrument. Pure sunlight was thrown into the upper half of the field for comparison, by means of the reflecting prism. Having adjusted the light so that no difference could be detected between the upper and lower halves of the field of view, the candle was placed in position in front of the slit. There was a very definite general absorption, most noticeable in those rays that are deficient in lamplight, especially about F and G, where also the spectrum of the reflected sunlight is brightest. The experiment is difficult owing to the necessity of reducing the brilliancy of the sunlight without so far reducing the angle of the illuminating ray that the hot air-currents may vitiate the result. But after many trials I satisfied myself that the more refrangible rays of light transmitted through a luminous flame are to some extent absorbed, the effect being stronger in proportion as the smoky part of the flame is approached.

Experiment 9.—It seemed evident that the reflection of the sunlight from the flame was due to its superior intensity; I therefore judged that, if I could lower the temperature of the carbon somewhat, I might get a visible reflection with light from other sources. I held an iron nail in the flame, and focused on the resulting smoke the light from a petroleum lamp. The spot of light was plainly visible, only not of a bluish white as with sunlight, but of a dirty yellow colour. It could be seen not only on the cold smoke, but also where it was of a bright cherry red; beyond that it became lost against the brightness of the incandescence. But the smoke, whether hot or cold, polarised the light exactly as the fine precipitates did.

Experiment 10.—In order to get rid of the disturbing effects of the light from the candle itself, I punched a hole in the middle of a tin plate, and placed it over the candle. The column of smoke coming up through the hole completely polarised the light thrown on it, whether from a lamp or from the sun, at right angles to the line of incidence. I then placed a little tuft of asbestos saturated with melted paraffin upon the hot plate. It gave off a dense smoke, indistinguishable to the eye from that of the burning candle. On applying the spectroscope, however, the difference was manifest. The light reflected by it was *not polarised*. I would therefore suggest that this polarisation test be the distinction between "steam," however dense, and a true "smoke." I have reason to believe that a polarising smoke only arises where the heat causes decomposition.

Experiment 11.—I placed the under side of the tin plate in the light, and found that the soot upon it reflected plane-polarised light in all directions at right angles to the line of incidence.

I now desired to ascertain if this power of reflecting light is confined to substances burning in the inner flame. It is difficult to make accurate observations as to the spectrum of the inner flame with an ordinary Bunsen burner, from the fact that it is completely surrounded by the outer flame; and this last, being but feebly luminous, gives only a very faint spectrum. I wished to make an arrangement by which the spectra of the two flames could be completely separated, while at the same time their intensity should be increased. Accordingly, I made a Bunsen burner with a rectilinear aperture, two inches long by an eighth of an inch wide, in place of the usual round tube. This gave me a broad flat flame, the edges of which I allowed to play each against a piece of well-annealed glass, so that I could look through the glass and see the flame edgeways. In this way I got a very strong spectrum of both the inner and the outer flames, perfectly distinct from each other, the ends of the flame being cut off by playing against the glass. The inner flame with its bright lines was thus completely separated from the outer with its soft, apparently continuous, spectrum: under sufficient pressure, the separation extended to the eighth of an inch or more. I could see no lines across this intervening space, except perhaps that in the violet: as to which I am not quite sure. Of the others I am certain, and I think the space is perfectly dark. As the glasses soon crack, I substituted another arrangement, which I hope still farther to perfect. In this flame I burnt a number of substances, keeping the image of the sun upon it all the while, and having the spectroscope with polarising prism, &c., arranged as in Experiment 5. I here give the results of two of the most interesting of these experiments.

Experiment 12.—I burnt on a piece of wire a mixture of copper sulphate and ammonium chloride. This compound, as is well known, gives a very beautiful and complex spectrum. When the mixture is held in the inner flame it turns dark, bubbles up, and burns like a piece of pitch, giving a continuous spectrum; and upon this flame, which never passes beyond the inner flame, the reflection of the sunlight may be seen and the Frauenhofer lines distinguished. There is also, at the same time, in addition to the beautiful blue-violet coloration of the outer flame, a curious "red smoke" right on the outer edge of it. But though in a dark room this looks far more like a solid precipitate, or true smoke, than the bright flame—though by daylight it looks so "smoky" that I thought it surely must give what I sought, a reflection in the outer flame—yet the sunlight passes through it without the slightest effect, save that it renders it invisible. The spectrum of this apparent smoke consists of groups of lines in the red.[1]

Experiment 13.—I now sought a substance that should be volatile in the inner flame and give a non-volatile oxide in the outer. I placed some zinc, which I found to be the most manageable metal for this purpose, in a small iron cup in the very centre of the flame. As soon as it boiled, flashes of white light appeared in the outer flame, and I was enabled to ascertain that these flashes gave a continuous spectrum and were also capable of reflecting sunlight, the reflected light being polarised, as in the other cases, in all directions at right angles to the line of incidence.

[1] In a recent experiment this "red smoke" gave a "soft" continuous spectrum from the extreme red to the yellow a little beyond *D*. It is very transient, and seems to be produced when the fused mass is drawn nearly out of the flame.

I venture to think, therefore, that the proof is fairly complete that the luminosity of a candle or gas flame proceeds from incandescent matter in a state of extremely fine division, because—

(*A*) Light can be reflected from it in the same way as from very fine particles of lac, sulphur, &c.

(*B*) The reflection begins with the violet rays when the precipitate first forms, and extends to the red as it becomes denser in the upper smoky part of the flame, the spectrum undergoing a similar change to that of the acidulated hyposulphite solution.

(*C*) There is no break in the phenomena from the commencement of incandescence to the cooling smoke and even the cold soot itself. The reflection is visibly produced by any rays, whether of the sun or from a lamp, that are more intense than those of the incandescent body; and I imagine that light that is less intense is still reflected, though it cannot be discerned.

(*D*) The spectrum of light transmitted through a flame is complementary to that reflected from it, as is also the case with a solution containing fine particles.

(*E*) The peculiar property of polarising all light reflected at right angles to the line of incidence which is considered the test of solid matter in extremely fine division is possessed by all flames giving what is known as the "solid" spectrum.

(*F*) Whenever a precipitate is actually formed by a reaction known to take place in either inner or outer flame, the resulting luminous flame has the optical properties described in this paper. Thus zinc, which produces these results only in the outer flame, gives evidence of the solidity of its oxide in the form of smoke. And with the mixture of copper sulphate and ammonium chloride it is not that part of the flame that looks most like smoke to the eye, but that which gives a "hard" continuous spectrum which is found capable of reflecting light.

I am still working on the lines indicated by these experiments, and though the foregoing is all I feel justified in publishing at present, it by no means contains all the suggestive results I have obtained in my endeavour to ascertain the cause of luminosity in gases and substances vaporised in the Bunsen flame. My time is very much occupied and my appliances limited: it may be long before I can complete my researches, so I have thought it well to make public my conclusions, so far as they go.

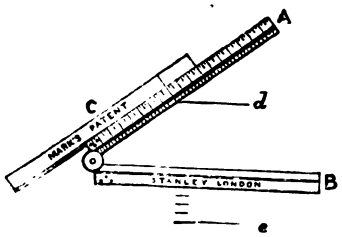
GEORGE J. BURCH

A LINE-DIVIDER

GALILEO'S proportional compasses are said to date from the year 1597. We infer that the instrument consisted of two arms, jointed, as in the accompanying figure, so that one arm could move freely about the joint. Each arm had a number of equal divisions (not necessarily of the same length on each arm), the zero point being at the joint. To divide a given length into five equal parts it is necessary to take an ordinary pair of compasses and measure the given length with these, then set the proportional compasses so that the fifth division on each arm may be at the given distance apart, then transfer with the ordinary compasses the distance between the unit divisions—this will be one-fifth of the given line. This seems to have been the manner of using the instrument employed by Galileo (cf. Marie, *Histoire des Sciences Mathématiques et Physiques*, tome iii. p. 108). Other modes of using will doubtless occur to most of our readers. The principle involved in this and similar instruments, and certainly in the one before us, is that of the proportionality of corresponding sides in similar triangles.

Our figure represents Miss Marks's patent line-divider for dividing any space into a number of equal parts. A B forms a hinged rule with a firm joint; each limb is ten inches in length (in the specimen we are describing), the limb B is bevelled, fronted with brass, and presents a straight edge, so that straight lines can be drawn along it. The limb A is also bevelled, and is divided on the bevelled edge and also on the top into eighty equal parts, so that we are enabled to divide a given length into any number of equal parts from two to eighty. A is fitted to slide in an undercut groove upon the plain rule C, which has a single line marked upon it, and is also provided with needle points on the under-side, to prevent it from slipping when placed in any position.

Suppose we take the case already considered. Slide C along A till the C line coincides with one of the lines on A, against which is the number 50. Place the corresponding line on the level of A on one end of the line to be



divided, then open out or close up the rule till the bevel of B passes through the other end of the line. Now press the points on the underside of C firmly into the paper, and slide A up till the number 4 on the line of reference is coincident with the line on C, and mark the point where the bevel of B meets the given line to be divided. Continue to move A up one division at a time till the whole line is divided. If we require lines to be drawn through the several points of division in a given constant direction, it is obvious that we must fix the instrument so that the bevel of B shall be initially in the given direction.

We have said enough to show how the divider is used, and it remains only to state that it appears to be a very handy instrument for architects, engineers, and practical drawing. Stanley, of Great Turnstile, Holborn, is the maker.

UNIVERSAL TIME AND THE RAILWAYS

ONE of the reasons why the Prime Meridian Conference met at Washington was that the United States possesses the greatest longitudinal extension of any country traversed by railway and telegraph lines, and it is quite in keeping with the spirit of American institutions that some of the most important measures necessary to carry out the resolutions of the Conference were taken by the railway men before the scientific men had begun their sittings. The action of the railway companies began as far back as 1883. It was a regular rebellion against the inconvenience of having more than half a hundred standards of railway time from east to west of the continent. At the Conference itself, Mr. W. F. Allen, one of the United States delegates, who has from the first taken the greatest interest in this special branch of the subject, brought the matter prominently before the Congress, stating what had been done. Since the Conference met, the suggestions primarily due to the railway authorities have been accepted by the Army Signal Corps and other public bodies, and from the east of Canada to the Pacific the Continent is now divided into five sections, each with its time standard, differing by one hour from those to the east and west. Thus we have Intercolonial time, Eastern time, Central time, Mountain time, and Pacific time, representing differences of one hour or 15° of longitude. We append map, and a paper by Mr. Allen, which we have receiv

from an esteemed correspondent, which will show at once the history of this movement and what has come of it.

I. On November 18, 1883, the principal railway lines of the United States and Canada adopted a new method of computing and recording time, for the purpose of securing *a uniform time standard* which should simplify the business of transportation and add to the convenience of travellers. It is almost wholly for purposes of travel and transportation that the majority of people have need of accurate time, and everywhere, except in very large cities, business has always been regulated by railroad time.

II. The defects of *the old system* of time standards were mainly as follows :—

(1) There were formerly more than fifty standards of railway time in the United States. Now there are fo four.

(2) The old standards differed from each other, whe they intersected, by all sorts of variations, errors, and od minutes. Now the differences between the standards a an exact hour, and the minutes and seconds are the sam in all four divisions.

(3) Formerly there were almost innumerable places which standards changed. Now the points of change a few in number, and always at prominent points of railwa departure.

(4) Formerly almost every railway centre had two three standards of time. Chicago used three; Kansa City had five; and St. Louis, where fourteen roads centre used six different standards.

III. In the plan which has now been adopted it was proposed :—

(1) That the same standard should govern as many railroads as possible.

(2) That the standards should not extend over so large an area of territory as to cause standard time to differ at any point by more than about thirty minutes from local time (mean solar time).

(3) That each standard should vary from the adjacent standards by the most readily-calculated difference, that of an even hour.

(4) That changes from one standard to another should be made at well-known points of departure.

(5) That these changes should be made at the termini of roads where changes naturally occur, except on the transcontinental lines, and in a few other unavoidable cases, where they should be made at the ends of divisions.

(6) That the 75th meridian west from Greenwich being almost precisely the central meridian for the system of roads using standards based upon the time of eastern cities, and the 90th meridian being equally central for the roads running by the time of western cities, the time of those meridians should be adopted for the territory which includes nearly 90 per cent. of our whole railway system. The hour meridians east and west of those named (the 60th on the east, and the 105th and 120th on the west) were found to be equally well adapted as central meridians for the roads in the section of country adjacent thereto.

IV. The problem in this country presented a feature nowhere else encountered. Standard time was introduced

throughout the island of Great Britain as long ago as the year 1848. When the railways demanded uniform time, and Greenwich time was adopted. France also has a uniform standard. But the continent of North America covers too many degrees of longitude to permit of the use of any one meridian as a single hour standard for all points between the two oceans. Under such a system there would be points where local time would differ from standard time by about two hours.

V. *The new system* divides the United States into four sections. At all places in the same section time is the same. The first section, which is governed by the time of the 75th meridian west from Greenwich, embraces all the territory between the Atlantic coast and Detroit, Pittsburg, Wheeling, Parkersburg, Huntington, Bristol, Augusta, and Charlestown, as indicated on the accompanying map (see next page). This is called *Eastern Time.* At 12.0 mid-day on the 75th meridian every clock and time-ball, from Calais to Pittsburg and from Quebec to Charlestown, indicates the hour of noon.

The second section is governed by the time of the 90th meridian, called *Central Time.* It includes all the territory from the western limits of the eastern time (that is, from Detroit, Pittsburg, Augusta, &c.) to Bismark, North Platt, Dodge City, &c. Time in this section is one hour slower than eastern time.

The third section extends from the last-named places westward to Heron (Montana), Ogden (Utah), the Needles (Arizona), &c. Time in this section is that of the 105th meridian (one hour slower than central time), and is denominated *Mountain Time.*

VI. At 12.0 noon in New York City the time at Chicago is 11 a.m., at Denver 10.0 a.m., and at Portland (Oregon) 9.0 a.m. By the old system at 12.0 noon in New York it was 11.05 in Chicago, 9.56 in Denver, and 8.46 in Portland.

VII. The adoption of a uniform standard of time by the railway lines has led to the *abandonment of local time* in nearly all the cities of the United States. The time of the 75th meridian was selected as the standard for the district of Columbia by Act of Congress, approved March 13, 1884.

It is encouraging to learn that, as was to have been expected, local time throughout the United States, as opposed to railway time, has already been abolished, and it is to be hoped, for the benefit of railway travellers on this side of the Atlantic, that the continent of Europe, from the extreme west of Spain to the Caspian, will soon be dealt with in the same manner.

NOTES

WE regret to state that Prof. Benjamin Silliman, of Yale College, died at Newhaven on the 13th inst., aged sixty-eight.

THE death is announced of Prof. Friedrich von Stein, at Prague, at the age of 67. He was appointed Professor of Zoology and Zootomy of the Prague University, an office which he occupied for thirty years.

THE death is also announced, at the age of fifty years, of Col. Roudaire, whose name is intimately associated with the project of a Saharan Inland Sea. Although strongly supported by M. de Lesseps, the scheme was opposed by the great number of competent scientific authorities. With the death of Col. Roudaire the scheme will probably fall to the ground.

THE Vice-Chancellor of Cambridge has appointed Mr. George John Romanes, M.A., F.R.S., to the office of Sir Robert Rede's lecturer for the ensuing year.

THE Royal Academy of Turin announces the foundation of a prize of the value of 12,000 francs for the most useful and striking discovery in anatomy, physiology, pathology, the exact sciences, history, geography, or statistics. The period within which the work must be done or the discovery made is from 1883 to December 31, 1886. Members of the Royal Academy or the Academy of Science in Turin are ineligible for the prize, the judges for which will be the Academy of Sciences of Turin.

THE Academy of Sciences, Berlin, announces the following subject for a prize of 2000 Marks, which, if sufficient merit be shown, will be awarded on the Leibnitz Anniversary in 1887 :—"A determination of the nature of the primary assimilation-products of carbon-dioxide in plants ; to be based upon suitable experiments and chemical investigations into the process in plants, when exposed to the influences of light ; as well as upon direct histological demonstrations of the form it assumes in the tissues of the plant. The first form assumed by the assimilation-product is to be distinguished from the succeeding ones which the substance passes through in the metabolism of the cell. The chemical formulæ are also to be given. It will be considered an approximation to the solution of the question, if, by going over the work that has been done already on this subject, it shall be shown by an accurate series of observations and experiments that the present theories concerning the process of assimilation in plants and the primary organic product of this process, are susceptible of a wider extension, or that they require to be limited by important qualifications." Essays may be written in German, Latin, French, English, or Italian, and must be forwarded before January 1, 1887.

FROM subsequent information with regard to the accident to Dr. Divers, Principal of the Imperial College of Engineering, Tokio, it appears that he had taken in his hand a bottle supposed to contain perchloride of phosphorus, but, finding the stopper fast, was heating the neck to release it, when it burst, the bottle disappearing as dust, and the contents as gas. Dr. Divers was nearly suffocated by the fumes, and one eye was injured. When the last mail left, it was not in a state to be critically examined ; but strong hopes are entertained that the sight will be restored. The accident is supposed to be due to the decomposition of the perchloride of phosphorus, which was old. Dr. Divers was at work on a paper on the theory of acids when the accident occurred.

THE undertaking to transport a whole Japanese village, with its shops, houses, and inhabitants, half round the globe to London, was a somewhat bold one for a private individual. But it has been performed with great thoroughness and success in the case of the Japanese village now on view at Knightsbridge. The houses are new and clean, which the tenements of Japanese villages always are not ; the small temple or shrine is rather more cleanly and ornamental than is usual with these structures in real life ; the wrestlers do not exhibit the physical characteristics which are so conspicuous, not to say disgusting, in the real Japanese wrestler ; and their methods of refreshing themselves between the bouts are more in accordance with European tastes. But, on the whole, home-loving English people have now an opportunity of seeing the Japanese at home, which they can never have without a journey to Japan itself. There is very little to note in the exhibition from a scientific point of view ; the inhabitants are fair average specimens of Japanese artisans and shopkeepers, so that the ethnologist will have a good opportunity of comparing his notions gathered from Miss Bird and other writers of the Japanese people with the reality. He can, in a measure, study the racial characteristics of the Japanese *in situ.*

THE Spanish earthquakes have continued to manifest themselves at intervals during the past week in the same area as that in which they first appeared. In connection with this phenomenon, the following extract from the report of the meeting of

the Spanish Natural History Society of January 7, 1885, has been forwarded to us from Madrid for publication:—Mr. Joseph Macpherson made the following remarks on the earthquakes in Andalusia:—"The earthquake which took place in the peninsula on the night of December 25 last, and which cannot yet be said to have ceased, has assumed a character of such intensity, and presents in its action such marked coincidences with the geological structure of this part of the world, that I think it will be interesting to enter into some detail with regard to the principal conclusions to be deduced from that phenomenon. Taking the whole peninsula, the disturbance may be divided off into three successive phases, viz.: one of relatively slight importance which occurred in the early morning of December 22, and which was confined to the western portion of the country, its effects being felt only in Galicia and Portugal; another, of the highest importance, which occurred three days later, namely, at 9 p.m. on the 25th of that month; while the third phase includes the oscillations which have taken place, and are still taking place, in the districts most severely affected by the earthquake of the 25th. That earthquake extended over a very considerable surface, the district affected to an appreciable degree including approximately, it would seem, the whole country lying between Cadiz and Cape de Gata and between Malaga and the Carpathian range. According to all the data known to us so far, the oscillations gained in intensity as they proceeded southwards from those mountain ranges, reaching their maximum of motion in the region lying between the mountains of Ronda and the Sierra Nevada. The shock was quite perceptible at Madrid, where it was strong enough to stop a few clocks and ring a few bells. The movement was apparently that of a pendulum, and its direction was from north to south. Two successive oscillations were observed separated by an interval of from three to four seconds, and each oscillation lasted from two to three seconds. The movement gained in intensity, as I have said, as it proceeded southwards, more especially after leaving the southern border of the central tableland limited by the fault of the valley of the Guadalquivir. Now, the interest of the phenomenon lies in the coincidence observable between its various manifestations and the geological structure of the peninsula. To make this clear, let me be permitted to offer a few observations on the subject of that geological structure. The archaic formations of the peninsula, with rare exceptions, lie in folds and faults running with singular consistency from south-west to north-east, and as an instance of this peculiarity I may mention the Carpathian range, which crosses the peninsula from east to west. After these archaic disturbances the Cambrian and Silurian deposits were likewise in their turn crumpled up into folds. These, however, run from north-west to south-east, that is to say, in a direction which forms almost a right angle to the earlier archaic folds. Concurrently with this general crumpling of the lower Palæozoic strata, there appeared in a broad zone great masses of granite, porphyry, diabase, and other kinds of rocks, which cross the peninsula from Galicia to the valley of the Guadalquivir, and which, geologically speaking, divides the peninsula into two distinct parts. This huge belt, which may be regarded as one of the most striking features of the peninsula of our day, cuts and divides the archaic formations, as this may be perceived at once in the central Carpathian range itself, which is interrupted between the Sierra de Gata and the Estrella range in Portugal. A study of the Mediterranean watershed of Andalusia will show the existence of two great mountain masses, chiefly formed of archaic deposits. One of these is known by the name of the Serrania de Ronda, and the other by that of the Sierra Nevada. Both run in a series of folds and faults from south-west to north-east, and between them there lies an interval filled up with palæozoic, secondary, and tertiary deposits. Towards the middle of this interval there rises up, like an island in the midst of these later deposits, a series of ridges running from north-west to south-east, and formed of archaic rocks. They are known by the name of the Sierra Tejea and Sierra Almijara, and the folds of these ranges, as in the case of the other archaic formations, run from south-west to north-east. It is clear, therefore, that this intermediary mountain mass is a segment of a more considerable archaic formation, separated from adjacent rocks through the subsidence of the ground on both sides. Owing to constant oscillations, this detached portion has been covered with the thick mantle of sediment which now overlays it, and its structure is easily accounted for as the result of that great fracture which crosses the peninsula from north-west to south-east, in the prolongation of which lies the region I am now describing. This fracture does not evidently end in the valley of the Guadalquivir, and though the surface be covered over by later deposits, it apparently extends to the country lying between the archaic mountain masses of the Serrania de Ronda and the Sierra Nevada, which it divides from one another, and whose ancient unity is testified by the Sierras Tejea and Almijara. The two principal coincidences observable between the phenomena of the earthquake and the geological structure of the peninsula are:—(1) That the disturbance of December 22 was confined to the regions lying to the west of the zone above described; and (2) that the most violent shocks of the earthquake of December 25 were experienced in the region intervening between the Sierra Nevada and the Serrania de Ronda, and precisely on the very belt which incloses the archaic mountain mass of the Sierras Tejea and Almijara. That part of Andalusia, broken and torn by the secular disturbances of our globe, has proved naturally the weakest, and has, therefore, been the most exposed to the shocks from which Andalusia has so terribly suffered. There stood Alhama, now prostrate in the river bed; there, Periana, a heap of ruins 3 m. high; there Albuñuelas, which exists no longer; there Zafarraya, Nerja, Torrox, and many other towns and villages; all testifying to the fragility of those faults, which though dating back to the Silurian period, are still apparently not completely welded.

MR. G. JOHNSTONE STONEY, F.R.S., Vice-President of the Royal Dublin Society, will give a discourse at the Royal Institution on Friday evening, February 6, on "How Thought presents itself in the Phenomena of Nature"; and on the following day (Saturday) he is to begin a course of three lectures upon the "Scale on which Nature works and the Character of some of her Operations." The following are the titles of the three lectures:—"Operations of Nature carried out on a Great Scale"; "Operations which go on between Molecules"; and "Operations which go on within Molecules, and the more Subtile Operations of Nature."

ACCORDING to *Science*, about 10 per cent. of the plants collected in the North-Western Mexican States by recent collectors prove to be new species.

MAY we suggest to the authorities of the British Museum the desirability of taking some means of letting the public interested in the matter know some little time beforehand when those lectures are to be delivered which are so regularly reported in the *Times*, but of the arrangements for which no one seems to know anything?

DR. J. A. FLEMING is about to give, at University College, Gower Street, a course of lectures on "Modern Applications of Electricity in the Arts." The lectures will be interspersed with practical demonstrations.

THE Electrical Exhibition, which was to take place at the Paris Observatory in the beginning of January, has been postponed to March 19.

THE thirty-eighth annual general meeting of the Institution of Mechanical Engineers will be on January 29 and 30, at 25, Great George Street, Westminster, by the kind permission of the Council of the Institution of Civil Engineers. The chair will be taken by the President at half past seven p.m. on each evening. The following reports and papers will be read and discussed, as far as time will admit:—Final report on experiments bearing upon the question of the condition in which carbon exists in steel, by Sir Frederick Abel, C.B., D.C.L., F.R.S.; second report of the research committee on friction; on recent improvements in wood-cutting machinery, by Mr. George Richards, of Manchester; on the history of paddle-wheel steam navigation, by Mr. Henry Sandham, of London; description of the Tower spherical engine, by Mr. R. Hammersley Heenan, of Manchester.

THE Dutch Government have issued the first part of their official report on the Krakatoa eruption. It deals with the history of the island prior to the occurrence, and the events of the catastrophe itself. The second part will deal with the scientific results of the investigation. The editor examined 1300 reports of eye-witnesses, and has endeavoured from them to construct a chronological statement of the events preceding and accompanying the eruption.

THE list of the conferences of the Sorbonne has been published for this year. On January 24 Dr. Brouardel lectures on the epidemics and protective measures; February 7, classification of celestial bodies according to their nature, by M. Faye; February 21, application of recent advances in physics to public works, by M. Gariel; March 14, architecture of the heavens, by M. Wolf; April 9, great volcanic catastrophes, by M. Velain.

WE are requested to state that Dr. William Pole, F.R.S., has been appointed Honorary Secretary of the Institution of Civil Engineers in the room of the late Mr. Charles Manby. The office of Secretary is filled, as formerly, by Mr. James Forrest. Mr. H. L. Antrobus has been re-appointed Treasurer.

MOST of the inhabitants of Leden, the *Standard* states, about a mile from Colchester, were awakened shortly after midnight on Sunday by what they believe to have been an earthquake. Much alarm was occasioned. The shock occurred at half-past twelve o'clock, and lasted about thirty seconds. The houses shook and the crockery rattled, but the shock was nothing like so severe as the one experienced last April. The shock seems to have extended as far north and east as Aldeburgh.

SEISMIC activity appears to have been exceedingly widespread recently. In the middle of November the first earthquake in ten years occurred at Monkden, in Manchuria. Both shocks, the present and one ten years ago, came from the same direction, viz. north-west to south-east, which, it is curious to note, is not the prevailing direction of the hill ranges, but at right angles to it. The Chinese in Manchuria are persuaded that warning of approaching earthquakes is given by the Coreans to the Chinese Government, and that the shaking of the earth is caused by the yawning of the great fish, on which the globe reposes.

IT is reported from Sundal and Öxendal, on the west coast of Norway, that a severe shock of earthquake was felt there at about 7 a.m. on December 28. The shock was so violent that the houses shook, and the people ran out terrified. It was impossible to tell in what direction the shock went. This phenomenon is remarkable for two reasons, viz. that it hardly ever occurs in Norway, and that it occurred on the day after the terrible earthquakes in Spain.

THE prospectus has been issued of the *American Journal of Archæology*. The Archæological Institute of America has recognised the *Journal* as its official organ. Among the specific objects of its editors will be:—(1) To afford to American scholars the means of taking active part in the progress of archæological science by the publication of papers embodying the results of original research; (2) To provide a careful and ample record of archæological discoveries and investigations in all parts of the world, and to furnish reports of the proceedings of archæological societies, summaries of important papers, reviews of books, &c.; (3) To bring to notice and to illustrate important works in the domain of archæology contained in our public museums and private collections, now little known. The following is a list of the editorial staff, so far as at present formed:—Advising Editor: Prof. Charles Eliot Norton, of Harvard College; Managing Editor: Dr. A. L. Frothingham, of Johns Hopkins University; Special Editors: Dr. A. Emerson, of Johns Hopkins University, Mr. T. W. Ludlow, of New York, Prof. Allan Marquand, of Princeton College, Mr. A. R. Marsh, of Harvard College, Mr. Charles C. Perkins, of Boston. The *Journal* will be published four times a year, and the numbers for each year will form an 8vo volume of about 360 pages. Messrs. Trübner and Co. will be the English agents.

AT Königsberg, in Prussia, will take place during the months of May to August of this year an International Industrial and Polytechnic Exhibition for machinery, motors, tools, appliances for mechanics, small manufacturers, &c. The following are some of the heads of groups under which exhibits will be classified—viz. (1) motors; (2) transmission appliances; (3) tools and implements for all branches of manufacture; (4) chemical and physical apparatus; (5) apparatus for technical education; (6) safety and protective appliances; (7) machinery and appliances for household purposes and for innkeepers; (8) agricultural implements and appliances. The Exhibition takes place under the authority of the Industrial Central Union of the province of East Prussia. Dr. N. Heinemann, of the new Athenæum Club, 3, Pall Mall East, has been appointed Special Commissioner of the Exhibition for England, and will give all necessary information to intending exhibitors.

THE annual meeting of the Association of Assistant Mistresses, which is confined to mistresses in girls' high schools, endowed, and proprietary schools, was held on Saturday at the North London Collegiate School for Girls. The President, Mrs. Hankin, of the Edgbaston High School, Birmingham, was in the chair. The discussion of the rules of the Association occupied a large proportion of the time. The Secretary's report showed that the work of the past year (the first of the Association's existence) had been chiefly that of organisation, whilst the Treasurer's report gave a hopeful account of the finances of the institution, there being a considerable balance in hand. It was resolved to appoint foreign and colonial correspondents, whose duty it should be to inform the Association of openings abroad, and a home correspondent, to whom assistant mistresses might apply, and to whom notices of vacancies might be sent. A plan for a lending library, to consist chiefly of voluntary loans of books, was approved, and a sub-committee was appointed to carry it into effect. A hope was expressed that publishers might be induced to present copies of educational works, and that any friends to the Association, leaving England for a time, might grant the use of their books during their absence. Mrs. Bryant, D.Sc., was elected President for the coming year. After the conclusion of business, the meeting proceeded to the discussion of papers on educational subjects. Miss Sharpe of Bradford read a paper on the training of teachers. Several papers were also read on the correction of exercises, describing the systems obtaining at different schools. It is from the discussion of such papers that the Association anticipates practical results: by their means, ide are circulated that would otherwise remain unknown to t majority, and hints given by which all interested in th

work will profit. Papers on educational subjects will be read at the spring meeting, which is to take place in the middle of April at the Girls' Grammar School, Bradford.

OLD residents of the California peninsula have noticed several varieties of birds near the sea coast that they have never before known to leave the mountains. This is supposed to indicate a severe winter, but the migration is more probably due to the prevailing scarcity of all kinds of seeds in the mountains this season.

ACCORDING to the report of the captain of a vessel which in December returned from Eskefjord, on the east coast of Iceland, showers of ashes fell on Eastland early in November. The deck of the ship was covered with a thin layer of ashes, probably caused by a volcanic eruption inland.

MR. W. HEWITT, Science Demonstrator to the Liverpool School Board, writes to us with reference to the "Itinerant" method of science teaching. The special instruction is, in Liverpool, he states, commenced with the children in the *fourth* standard, and by this means deals with more than double the number of children who would be included were the commencement deferred until the fifth standard, as appears to be the case in Birmingham. There is every reason to believe, Mr. Hewitt thinks, that the preliminary instruction in the fourth standard is a very important part of the intellectual training which it is the object of the system as a whole to give. The stages of instruction in each subject are kept quite distinct throughout, and are always taken in the same order. The children on commencing the subject take up the first stage, and proceed in the following year to the second stage, and so on through a systematic and carefully-graduated three (or four) years' course of instruction in elementary science.

THE hatching of lobster and fish is making great progress in Norway. Thus, last year the Association for the Promotion of the Norwegian Fisheries hatched 7,000,000 fish, chiefly cod and haddock, at their establishment of Arendal, in the Christiania fjord, and this winter between 50,000,000 and 60,000,000 more will probably be turned out. The experiments, which were made of placing the ova of lobster in hatching apparatus, have been attended with great success, and show that they may be turned out by the million in this manner. As private enterprise cannot be expected to undertake these operations from year to year on a large scale all along the coast, the Association have petitioned for Government support, which will, it is expected, be readily forthcoming, as the Norwegians now clearly see of what enormous benefit to the nation these operations are.

MR. NEWALL asks us to state that in his note on "The *Jeannette* Drift" (vol. xxxi. p. 102), the word *knots* should be *nauts*, a *naut* being a geographical mile of 60 to a degree. It is a much more convenient measure than the mile of 1760 yards, for it contains 1000 fathoms, or ten cables of 100 fathoms each, as used in the navy. It is the only decimal measure used in any Government department! *Knot* is a mark on a line used on board ship, having the same proportion to a *naut* which a half-minute glass has to an hour, or the 1/120th part of a naut; so, when 10 knots pass out during one turn of the glass, the sailor means that the vessel is passing through the water at 10 nauts an hour.

THE additions to the Zoological Society's Gardens during the past week include a Golden Eagle (*Aquila chrysaetos*) from Sutherlandshire, presented by Col. E. D. Hunt; a Crossbill (*Loxia curvirostra*), British, presented by Mr. G. Skegg; seven Bramblings (*Fringilla montifringilla*), two Chaffinches (*Fringilla cœlebs*), a Tree Sparrow (*Passer montanus*), a Black-headed Bunting (*Emberiza melanocephala*) from Norfolk, presented by Mr. T. E. Gunn; a Nilotic Crocodile (*Crocodilus vulgaris*) from Africa, presented by Mr. H. F. Cree; a Brush-tailed Kangaroo (*Petrogale penicillata* ♂) from New South Wales, a Golden-crowned Conure (*Conurus aureus*) from South-East Brazil, deposited; two Striated Tanagers (*Tanagra striata*) from Buenos Ayres, two Siskins (*Chrysomitris spinus*), British, purchased; a Virginian Fox (*Vulpes virginianus*) from North America, received in exchange.

OUR ASTRONOMICAL COLUMN

COMETS OF SHORT PERIOD. (1) ENCKE'S COMET.—The following ephemeris of this comet for February is founded upon Dr. Backlund's elements, which the January observations show to be very exact:—

At 6h. Greenwich Mean Time

1885	R.A. h. m. s.	Decl.	Log. distance from Earth	Log. distance from Sun

(2) BARNARD'S COMET.—Dr. Berberich, of Berlin, has made a new determination of the orbit of this comet from three normal positions deduced from observations extending over a period of three months. The sidereal revolution is now found to occupy 1958·9 days, or 5·363 years. In heliocentric longitude 343° 46′, the distance of the comet from the orbit of Mars is only 0·0079, and a revolution but slightly differing from that obtained by Dr. Berberich would have caused a very close approach of the two bodies as lately as the end of 1873 or beginning of 1874. The distance of the comet at aphelion from the orbit of Jupiter is 0·572. As previously remarked, much interest attaches to this comet from the similarity of the elements of its orbit to those of "the lost comet of De Vico," observed in the autumn of 1844.

(3) WOLF'S COMET.—Dr. Tempel, writing from Arcetri on the 4th inst., describes this comet as being still "sehr hell mit leicht zu beobachtendem Kerne." Considering that accurate observation commenced on September 20, the mean motion may be expected to be pretty exactly defined by the observations at this appearance, and the comet's orbit previous to the near approach to the planet Jupiter in 1875 may be investigated, with probability of a reliable result, without waiting for observations at its next return to perihelion in 1891.

GEOGRAPHICAL NOTES

THE *Bulletin de la Société de Géographie* for the last quarter of 1884 is largely occupied with the geography of the Far East. Two members of the foreign mission body communicate papers on Tonquin, both accompanied by maps. Père Pinabel writes on some "savage peoples" dependent on Tonquin. The expression "savage" is explained to mean nothing more than mountaineers. The tribes here described inhabit the mountains of the province of Thagne-hoa, between the rivers Mau and Chou, which is the most southern province of the delta of the Red

River, and not far from the Annamite border. The tribes called Phon-tays, live in a sort of semi-independence, like the Laos tribes, in the mountains on the Siamese frontiers. A third tribe inhabiting the region is called by Père Pinabel the Méos (Mois?), and are said by him to be in all probability the aboriginal Miao-tsze of South-Western China, although whether he has any ground for this belief beyond the resemblance of the names does not appear. At any rate, it is evident from their customs and language that they are Chinese. A fourth tribe is called the Sas, of whom nothing appears to be known except that it fled to the borders of Annam during one of the numerous wars of that region. A long and tolerably detailed account of the manners and customs of the Phon-tays is given, and shorter ones of those of the Mois and Sas. They are all the more interesting that the writer appears to have no idea of ethnology, and therefore is not on the look-out for parallels elsewhere, but records everything with simplicity and directness. Père Blanck's experiences lay also in the Laos States, on the frontiers of Siam and Tonquin, but to the south of those of his colleague. His paper is simply a record of his journeys among the "savages" in the mountains between the province of Nghé-Ane, the most southern province of Tonquin bordering on Annam, and the Mei Kong River. Both these papers are taken from the reports of the *missions étrangères*. M. du Cailland describes the Quang-si, or Kwang-si, the province of China adjoining Tonquin, and that from which the greater part of the Chinese invading force is drawn. The writer discusses the routes from Langson into China, the river-system of Kwang-si, its administrative divisions, its ethnography, recent history, and the Catholic propaganda there. According to M. du Cailland, the Chinese population there is nothing more than a colony of Cantonese amongst the vast numbers of Miao-tsze and Laos in the western portion. Unfortunately, the writer has omitted his authorities for this statement, although his references in other portions of the paper are somewhat copious. It would be of great interest to learn on what grounds the wealthiest and most populous province but one of Southern China is believed to be only a Cantonese colony, while the Miao-tsze, who are generally believed to exist only in small and weak communities scattered over the central part of South-Western China, are masters of this vast district. The geography and ethnography of China must be rewritten, if M. du Cailland is accurate in this portion of his paper.—M. Huber continues his account of his journey in Central Arabia, which has been already noticed.—Prince Roland Bonaparte describes fourteen voyages to the coasts of New Guinea, made by Dutch Government vessels, between 1876 and 1883. They went chiefly from Ternate. Each voyage is described in detail, apparently from official sources. The conclusion of the paper is that it is easy to see from this account that the Dutch have annexed in a definite manner the eastern part of New Guinea to their empire in the Malay Archipelago.—M. Simonin discusses the progress of the Australian colonies commercially and politically.

AT the last meeting of the Gesellschaft für Erdkunde in Berlin (January 3) Dr. Steinmann read a paper on his journeys in Southern Patagonia. In 1882 he went as geological assistant to the fourth German expedition to Punta Arenas, mainly with the object of studying the Southern Cordilleras. What struck him particularly here was the extraordinary difference in the plant forms to those on the Southern Cordilleras, while on the western slopes vegetation is rich in forms, the climate of the steppes reigns on the eastern side. From a geological point of view, the southern point of America is extremely simple in its build, but it is of a different character on the east and west. On the east chalk formations occur almost entirely, while on the west, where there are innumerable islands, there is nothing but granite and crystalline rocks. Although the configuration of the coast has been studied thoroughly by the English, Dr. Steinmann thinks that many important questions have still to be settled; for instance, whether Laguna Blanca, lying to the north-east of the settlement Kyrsing Water, has an outlet to the west. Ultimately the lecturer reached the Laguna of the third settlement of Santa Cruz, of which it may with certainty be said that was connected until recently with the Pacific Ocean. It may also be concluded that at that time the mainland was much more cut up by channels and waterways than it is now. In May 1883 Dr. Steinmann visited, in the company of Fuegian seal-hunters, the islands south of the Straits of Magellan, including Tierra del Fuego. Ultimately, he made his way from the southern point of America to Bolivia, and here continued his investigations.

THE Society of Naturalists in St. Petersburg has received permission to despatch several of its members to join the Russian representatives on the Afghan Boundary Commission, with the view to the scientific exploration of Central Asia. The English Commission, which is now on the spot, has, it will be remembered, a geologist, a naturalist, and topographers amongst its number.

THE *Daily Telegraph* is publishing a series of articles descriptive of the Kilimanjaro expedition, "by its leader," Mr. H. H. Johnston. They are full of interesting detail.

WITH the commencement of the new year *L'Exploration* has taken a new form and a new title. It is now called *La Gazette géographique et l'Exploration*, and is about double its former size, the pages being larger and arranged in double columns. We trust that with this improvement there may be a corresponding advance in its usefulness as a geographical journal.

Petermann for January contains an article and map on the journey of the pundit A—— R—— in Eastern Thibet during the years 1878–82. Dr. Richard Lüddecke writes on the Italian emigration of 1883 from official sources. France takes nearly half of the emigration to European countries, while the State of La Plata and North America take the largest share of the extra-European emigration. Dr. Pauli writes on the Cameroons, and Herr Regel describes a journey from Charjui by Merv to Pandy, and back to Samarkand.

GEOLOGY OF AFGHANISTAN

THE *Times*, in the letter from its correspondent with the Afghan Boundary Commission, publishes the following notes supplied by Mr. Griesbach, of the Indian Geological Survey:—

"The hill ranges between Kushkak and Pahri in the Herat valley are all apparently composed of rocks belonging to the Cretaceous and younger periods. So far as I could judge, the ranges are formed by a series of parallel anticlinal folds of the Upper Cretaceous rocks, which in this part of Afghanistan (as in a great part of Persia) are hippuritic beds. They are mostly limestones, dark gray to white, and contain fossils in abundance, among which several species of hippurites are the commonest. The igneous rocks which play such an important part within the hippurite area in the Candahar district were also met with here under exactly the same conditions. Basic rocks (trap) are intimately connected with the Cretaceous limestones in this area also, and it would be impossible to distinguish them on anything but a very detailed geological map. Here also the limestone near the contact with the trap (and other igneous rocks) has been converted into a white, fine-grained marble, much used by the natives of Southern Afghanistan for monumental purposes. But by far the most interesting of the igneous rocks is a syenitic granite which appears in several patches. The Karez-i-Dasht is composed entirely of this rock, which is seen to be capped by trap in the surrounding hill ranges. Its age is most probably younger than that of the trap through which it has burst. This group of rocks, with the exception of patches of younger Tertiary rocks, form all the ranges up to and including part of the Chillingak range and pass (near Pahri). The latter range, in which the conspicuous Doshakh peaks are situated, is of great geological interest. It is an anticlinal fold, the centre and northern axis of which is formed by Palæozoic rocks; so far, I have only been able to detect Carboniferous fossils in a series of dark blue limestone beds, but it is quite possible that older groups are also there. The ravine leading to the high points south of Robat-i-Pai Ziarat has excavated its course through Carboniferous beds only. The beds dip north and below the younger gravels and fan deposits of the Heri Rud. But on the right bank of the valley, rocks appear again of an entirely different look, and it is quite possible that members of the lower Mesozoic system are represented there. The southern flank of the Chillingak range is formed only by Cretaceous beds—sandstones and shales of the Kojak type, overlaid with hippuritic limestone near Pahri. The connection of these beds with the Palæozoic strata of the centre is quite hidden. The older river deposits and Dasht beds are clays, sandstone, and conglomerates much of the same character as already described from the Helmund. They form thick deposits south of Pahri and in the Heri Rud Valley, and I have found remains of mammalian bones in the

I believe them to belong to the upper beds of the Siwalik series. In connection with the notes which I was enabled to make during the very hasty examination of the ground travelled over, two facts seem to me to be of considerable importance. The first is the reappearance of older strata than Cretaceous, and strata of distinctly a Himalayan type. One of the great problems of Asiatic stratigraphy is the exact connection of the sedimentary rocks of the North-West Himalayas with the system of the Caucasus, which is again only a continuation of the Alpine system; whether or not the Hindoo Koosh may be looked upon as a continuation of our North-West Himalayas can only be decided after an examination of its geotectonic features. The connecting link, so to speak, has yet to be found. But the finding of true Carboniferous marine beds containing *Productus semireticulatus* in a range which belongs to the Hindoo Koosh system is a distinct step towards the solving of the great stratigraphical problem of Central Asia. The second fact is of rather an economic than purely scientific interest. I found at more than one place along the route an altered rock near the contact of the hippuritic limestone and the igneous rocks, which in character resembles exactly the gangue in which at Candahar the gold and other minerals occur. So I believe that a careful search would certainly reveal similar ore-deposits in the Sabzawar and Herat districts. I may here mention again that the contact rocks in the Candahar district contain exactly the same minerals as do the altered hippuritic limestone beds of the Banat in Hungary, which also have been disturbed by young granitic rocks."

The same Correspondent, in a previous letter, describes the journey across Seistan from Khwaja Ali to Lash Juwan. The geological features of this part of Seistan are, according to Mr. Griesbach, extremely simple. Only post-tertiary and recent deposits were met with; the former are fluviatile beds, mostly clays, soft sandstones, and gravels, in character much the same as those forming the tableland of Handesin Tibet, and probably belonging to the same age. The drainage of the area during post-tertiary times seems to have been generally identical with the present one, though, perhaps, of a more extended nature. The recent gravel beds and conglomerates containing worn material from the neighbouring hill ranges are found in the Farah Rud and the Kash Rudak in considerable thickness, capping the underlying clays and sandstones of post-tertiary age. Locally, the conglomerate is replaced by a hard limestone breccia, as for instance at Galichah and also the Helmund. But the general character of this deposit is that of the Indus valley gravels, which are seen to overlie unconformably the younger Siwaliks along the Marri and Bugti hills and the Suliman range. They are found of course within the area of the present drainage. Of useful minerals, only gypsum exists, which is found in the post-tertiary clays, fills fissures and joints, and may perhaps also be found in larger masses. Apparently it is made use of for the manufacture of Gutch or plaster; traces of diggings for it are found near Lash.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The following scheme of lectures and classes in Natural Science has been issued by the Faculty for Lent Term, 1885:—

In the Physical Department of the Museum Prof. Clifton continues his course on the Galvanometer and Ohm's Law. Practical instruction in Physics is given by the Professor and by Messrs. Walker and Selby. Mr. Walker lectures on the Theory of Errors, and Mr. Selby, on Elementary Mechanics. At Christchurch Mr. Haynes lectures on Electrodynamics, and has a class for practical instruction in Electrical Measurements. At Balliol Mr. Dixon lectures on Elementary Magnetism and Electricity.

In the Chemical Department of the Museum Dr. Odling continues his course on the Aliphatic Compounds. Mr. Fisher lectures on Inorganic, and Dr. Watts on Organic, Chemistry. At Christchurch Mr. Harcourt lectures on the Non-Metallic Elements, and at University Mr. Veley lectures on Physical Chemistry.

In the Morphological Department of the Museum Prof. Moseley continues his course on the Comparative Anatomy of the Invertebrata. After each lecture special instruction is given in illustration of the lecture. Dr. Hickson lectures on Animal Morphology, Mr. Barclay-Thompson on the Anatomy of Mammalia, Mr. Hatchett Jackson on the Principles of Comparative Embryology and Development, and Mr. Poulton on the Distribution of Animals.

In the Physiological Department of the Museum Prof. Burdon-Sanderson lectures on the Nervous System, and practical instruction is given by the Professor and Messrs. Dixey and Gotch.

In the Botanic Garden Prof. Bayley Balfour lectures on Elementary Morphology and Physiology, and on the Morphology of the Vascular Cryptogams. Prof. Gilbert lectures on the Result of Field Experiments.

Dr. Tylor lectures on the Early History of Arts and Sciences; Prof. Maskelyne on the Rectangular-axed Crystal Systems; Prof. Prestwich on the Palæozoic and Mesozoic Series.

It is rumoured that the grant to carry on the new physiological laboratory under Prof. Burdon-Sanderson will be opposed in Convocation by the anti-vivisectionists. If this should turn out to be true, it behoves all members of Convocation who side with the advancement of science to come up and record their votes.

CAMBRIDGE.—The Board for Physics and Chemistry announces the following lectures for this term:—

Chemistry: Prof. Liveing, General Course; Prof. Dewar, Organic Chemistry; Mr. Main, St. John's, General Course; Mr. Pattison Muir, Cains, General Principles, advanced, especially Physical Chemistry; and Elementary Course for 1st M.B.; Mr. Scott (Prof. Dewar's assistant) Elementary Organic Chemistry; Mr. Heycock, King's, Chemical Philosophy for Tripos, Part I.; Practical Chemistry, Mr. Sell and Mr. Fenton, three courses of demonstrations, for medical students, Tripos Part I. and Tripos Part II.; Mr. Robinson, Chemistry as applied to Agriculture; Sidney College Laboratory, Demonstrations for 1st M.B., with explanatory lectures.

Physics: Prof. Stokes, Hydrodynamics; Prof. Thomson, Magnetism; Mr. Atkinson, Trinity Hall, Heat and Hydrostatics; Mr. Glazebrook and Mr. Shaw, Elementary and Advanced Physics; Mr. Hart, St. John's, Light and Electricity, elementary and advanced; Practical Physics, Demonstrations in Cavendish Laboratory, three courses.

Mineralogy: Prof. Lewis, Lectures and Demonstrations.

Mechanism: Prof. Stuart, Mechanism and Applied Mechanics, and Theory of Structures; Mr. Lyon, Elementary Mathematics, and Statics and Dynamics.

The Board for Biology and Geology publish the following list of lectures:—

Geology: Prof. Hughes, Pleistocene, with special reference to Prehistoric Archæology; Dr. R. D. Roberts, Physiography, and Class Work; Mr. Marr, Geological Evolution; Mr. T. Roberts, Palæontology; Mr. Teall, Advanced Petrology; Mr. Harker, Elementary Petrology and Class Work; Prof. Hughes, Field Lectures.

Botany: Dr. Vines, General Elementary Course, with practical work; Mr. Gardiner, Anatomy of Plants, advanced, with practical work; Dr. F. Darwin, General Biology of Plants; Mr. J. W. Hicks Sidney, Elementary Course; Mr. Potter, Classification of Gymnosperms and Monocotyledons.

Elementary Biology: Dr. Vines and Mr. Sedgwick.

Zoology: Prof. Newton, Geographical Distribution of Vertebrata; Mr. Weldon, Practical Morphology, Invertebrata; Mr. Sedgwick, Anatomy and Embryology of Vertebrata, elementary; Mr. Harmer, Osteology of Vertebrata, and advanced course on Arthropoda; Mr. Gadow, Palæontology and Affinities of Groups of Mammalia.

Physiology: Prof. Foster, Elementary Course; Mr. Lea, Chemical Physiology; Mr. Langley, Advanced Course; Dr. Gaskell, Circulation and Respiration, advanced; Mr. Hill, Class for 2nd M.B.

Human Anatomy: Prof. Macalister, Organs of Circulation and Respiration; Demonstrations in Osteology.

The Board for Mathematics announces the following lectures on higher mathematics this term:—Prof. Stokes, Hydrodynamics; Prof. Adams, Lunar Theory; Prof. Thomson, Trinity College, Electromagnetism; Mr. Hobson, Christ's, Planetary Theory; Mr. Glazebrook, Theory of Light; Mr. Forsyth, Functions of Complex Variables; Dr. Peasn, Analysis, Definite Integrals, Calculus of Variations and Differential Equations; Mr. Mollison, Fourier's Series and Conduction of Heat; Mr. Pendlebury, Analytical Optics; Dr. Routh, Attractions and the Figure of the Earth; Mr. Stearn, Electrostatics.

Mr. G. J. Romanes, LL.D., F.R.S., has been appointed to deliver the Rede Lecture this year.

R. E. Fry, Clifton College, has been elected to a Natural Science Open Exhibition at King's; W. J. Elliott, Newcastle

School, Staffs., and A. E. Potter, Yorkshire College of Science, to Entrance Scholarships at Christ's College; H. Bury, third year, and F. W. Oliver, second year, to Foundation Scholarships at Trinity College.

S. F. Dufton, Grammar School, Bradford, has been elected to an Open Exhibition for Natural Science at Trinity College, and A. E. Mayeur, St. Paul's, to an additional Exhibition.

SCIENTIFIC SERIALS

Journal of the Franklin Institute, 708, December, 1884.—G. Forbes, dynamo-electric machinery; a full report of the lecture given by Prof. Forbes at the Philadelphia Exhibition.—R. H. Thurston, steam boilers as magazines of explosive energy. This paper contains lengthy numerical tables of the energy, expressed both in foot-pounds and in kilogrammetres, stored up in boilers containing given weight of water or steam at given pressures. According to these calculations a Lancashire two-flue boiler holding three tons of water working at 37 lbs. of steam pressure would, by its explosion, liberate sufficient energy to blow itself nearly 2½ miles high, with an initial velocity of 900 feet per second.—E. J. Houston, glimpses of the International Electrical Exhibition, Nos. 2 and 3. These papers give accounts of Dolbear's electrostatic system of telephony, and of Gray's telephonic inventions, with numerous illustrations.—L. d'Auria, the earth's ellipticity; a reply to Prof. Chase.—Standard sizes of belt heads and nuts, a reply by Mr. Coleman Sellers to Mr. Simmonds.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, Nov. 27, 1884.—"Notes on the Microscopic Structure of some Rocks from the Andes of Ecuador, collected by E. Whymper. No. V. (conclusion). Altar, Illiniza, Sincholagua, Cotocachi, Sara-urcu, &c." By Prof. T. G. Bonney, D.Sc., F.R.S.

The microscopic structure of rocks from the first four of these mountains was described, the specimens being less numerous than in some of the former cases. Altar, Sincholagua, and Cotocachi furnished augite-andesites, mostly hypersthenic ferous; Illiniza, micaceous and hornblendic augite-andesites. Sara-urcu was not a volcanic mountain, the specimens all being metamorphic rocks, varieties of gneiss and schists, similar to those which occur among the less ancient metamorphic rocks of the Alps and the Scotch Highlands; hence, probably, Archæan, but not the very oldest Archæan. A few miscellaneous specimens were also described, and the paper concluded with some general remarks and a summary of results.

January 15.—"On the Chemical Composition of the Cartilage occurring in certain Invertebrate Animals." By W. D. Halliburton, M.D., B.Sc. (Lond.), Sharpey Physiological Scholar, University College, London. Communicated by Prof. E. A. Schäfer, F.R.S. (from the Physiological Laboratory, University College, London).

At Prof. Lankester's suggestion I have submitted to chemical analysis the cartilages occurring in Sepia and in Limulus.

The basis of the cartilage is a chondrin-like body which gives the reactions of mucin and gelatin (indeed, chondrin, as it occurs in the ordinary hyaline cartilage of Vertebrates, is now regarded by many as a mechanical mixture of these two bodies). But in the cartilages of the two Invertebrates in question the gelatinous element is exceedingly small, and no gelatinisation occurs on the cooling of the hot watery extract.

In addition to this, however, the cartilage of both these animals differs from that of Vertebrates in containing a certain small percentage of chitin. In the case of Limulus 1·01 per cent., and of Sepia 1·22 per cent., of chitin, in the dry state is present.

I have also demonstrated that chitin exists in the liver of the king crab, though whether in the connective tissue or in the liver cells themselves I cannot say. (The connective tissue element is very abundant in the liver of this animal, and it seems probable, looking at the part that chitin plays as a supporting structure in these animals, that it really forms in this instance a partial basis for the connective tissue.)

The way in which chitin was demonstrated to exist was the same in all three cases, viz.:—

(1) After digesting with potash, a residue insoluble in boiling alkalies remains behind.

(2) This residue, which, when washed and dried, is obtainable in a white amorphous condition, is insoluble in weak acids; but in concentrated mineral acids it is soluble in the cold.

(3) On boiling the solution in sulphuric acid, a body which has the power of reducing cupric salts is formed.

(4) On boiling the solution in hydrochloric acid it turns brown, and on evaporating this solution to dryness a body crystallises out which has all the properties of hydrochlorate of glycosamine.

(I prepared some of this body from the chitin contained in the exoskeleton of cockroaches, and also obtained from Prof. Lankester some crystals of the same body which Prof. Gamgee had kindly sent him.)

I was (thus) enabled to compare the crystalline body I had obtained from the invertebrate cartilage with that of the pure hydrochlorate of glycosamine, and they were found to agree in the following points:—

(*a*) Crystalline form: rhombic prisms of the monoclinic system; measurement of the angles gave the same result in all cases.

(*b*) Action of polarised light: *nil.*

(*c*) Solubilities: easily soluble in water, soluble with difficulty in alcohol.

These results are especially interesting as showing that chitin is not a body which is exclusively epiblastic in origin, but in these three instances at least occurs in mesoblastic structures.

Mathematical Society, January 8.—J. W. L. Glaisher, F.R.S., President, in the chair.—Messrs. F. R. Barrell, S. O. Roberts, and Prof. M. N. Dutt, St. Stephen's College, Delhi, were elected members. The Rev. T. C. Simmons was admitted into the Society.—Prof. M. J. M. Hill read a paper on the differential equations of cylindrical and annular vortices.—The Rev. R. Harley, F.R.S., spoke on criticoids.—The following further communications were made:—Multiplication of symmetric functions, by Capt. Macmahon, R.A.—Note on symmetrical determinants, by A. Buchheim.—Results in elliptic functions, by the President (J. J. Walker, F.R.S., Vice-President, in the chair).—Mr. Tucker read a second note by Prof. Cayley, F.R.S., on the binomial equation $x^5 - 1 = 0$; quinquisection, and communicated a second paper, by H. MacColl, on the limits of multiple integrals.

Victoria Institute, January 19.—A paper on the historical evidences of the Abramic migration was read by Mr. W. Boscarven, in which he gave extracts from the new translations of some tablets which had been discovered by Mr. Rassam during his last visit to the East. These extracts contained a large number of names of persons and cities mentioned in the Bible record of the times to which they referred.

EDINBURGH

Royal Society, January 5.—E. Sang, LL.D., Vice-President, in the chair.—Mr. Harvey Gibson submitted a paper on the anatomy of *Patella vulgata*.—Mr. W. W. J. Nicol read a paper on a theory of solution. Solution of a salt in a liquid results from the attraction of the molecules of the liquid for a molecule of the salt exceeding the attraction of the molecules of salt for one another. Saturation ensues when these attractions are balanced. The theory explains variation of solubility with rise of temperature. Mr. Nicol brought forward experimental evidence in support of his views.—Mr. H. R. Mill, chemist to the Granton Marine Station, read a paper on the salinity of the water of the Firth of Forth. Results were given, showing the variation of salinity along the Firth for high and low water.

PARIS

Academy of Sciences, January 12.—M. Bouley, President, in the chair.—Thermo chemical experiments with phosphorous fluoride, a new gas recently discovered by M. Moissan, by M. Berthelot.—Anatomical description of *Ganidia Garnotii*, Payrandeau, a species of Ganidia very abundant on the coast of Algeria, by M. de Lacaze-Duthiers.—Report on M. Luvini's two memoirs dealing with the formation of hailstones and the development of electricity during thunderstorms, by the Commissioners, MM. Becquerel and Faye.—On the formation of toxic alkaloids in cholera patients, by M. A. Villiers. Experiments made on two victims of cholera soon after death enabled the author to determine the presence of an alkaloid clearly characterised by its alkaline and chemical reactions. It is found chiefly in the intestine, and also in small quantities

in the region of the loins, but is completely absent from the blood and liver. Its study may yield important results for the treatment of cholera, and must possess great interest for toxicologists.—Observations of Encke's comet made at the Paris Observatory (equatorial of the West Tower), by M. G. Bigourdan.—Note on the theory of periodic transformations, by M. S. Kantor.—On some partially-derived linear equations of the second order, by M. Lucien Levy.—On the simultaneous effects of rotatory force and of double refraction, by M. Gouy. The author finds that these effects are in every respect conformable to those resulting from the hypothesis of Airy, that they may be completed by determining the values of K and B, and generalised by extending them to other mediums besides quartz.—Action of boric acid on some coloured reagents, by M. A. Joly.—On the hydrates of the sesquichloride of chromium, by M. L. Godefroy.—On the alkaline ferrocyanates and their combinations with the chlorohydrate of ammoniac, by MM. A. Etard and G. Bemont.—On a combination of acetic ether and the chloride of calcium, by M. J. Alsin-Le Cann. An analysis is here given of this compound, which was first indicated by Liebig.—On three new compounds of iridium, yielded by the combination of the perchloride of iridium, $IrCl_4$, with the hydrochlorates of mono-, di-, and trimethylamine, and corresponding in their composition to the chloro-iridate of ammoniac, by M. C. Vincent.—On various haloid derivatives from substitutes of propionic acid: chloruretted and ioduretted derivatives, by M. L. Henry.—On the significance of the polarimetric experiments made with the solution of cotton in Schweizer's liquid, by M. A. Béchamp.—On the influence of sunshine on the vitality of the germs of microbes, by M. E. Duclaux. From experiments made with *Tyrothrix tenuis*, cultivated in milk and Liebig's extract, the author finds that the light of the sun is fifty times more destructive than its heat, and its hygienic properties are thus fully confirmed.—Studies on the head and mouth of the larvæ of insects, by M. A. Barthelemy.—On some points in the anatomy of the Cidaridæ of the genus Dorocidaris, by M. Prouho.—On a marine Hemiptera, *Ectrychius Bonnardi*, Signaret, by M. R. Koehler.—On a venous cirrhosis determined in the rabbit by *Cysticercus pisiformis* (Auct.), and in connection therewith on the embolic origin of certain gigantic cellules, by M. Laulanié.—On a disease of the carob plant causing hypertrophy of certain parts analogous to the so-called malady of "la loupe" in the olive, by M. L. Savastano.—On the actual value of the magnetic elements at the Observatory of the Parc Saint-Maur, by M. Th. Mourceau.—On the earthquakes that occurred in Andalusia on December 25, 1884, and the following weeks, by M. Macpherson, with remarks by M. Daubrée.—On the ascending movement observed in certain waterspouts, by M. E. Vibert.

BERLIN

Meteorological Society, December 2, 1884.—Dr. Lœwenherz, after briefly sketching the history of the invention of the thermometer and the early improvements made on it, showed a large number of different constructions of the column and the inclosure thermometer for meteorological purposes, comprising the common as well as the maximum and minimum thermometer, and, in concluding his address, discussed the production of thermometers, the successive stages of which he illustrated by bringing forward glasses connected respectively with these.—Dr. Vettin spoke on the observations of clouds, and described an apparatus for measuring their height. Suppose the cloud projected to a distance of four miles, it then possessed at that distance a "projected" speed, in its actual height it possessed the actual speed, and from these two data the actual height could be calculated according to the proportion; the projected height H is to the actual height A as the projected speed C is to the actual speed *c*. The actual speed was measured by Dr. Vettin from the movement of the shadows of clouds, which he could in most cases determine directly by means of the sharp edges of the shadows cast on a large field of vision, where the objects and their distance from each other were known to him. In the case of cirrus clouds, again, the wandering of the darker and brighter spots along a street could mostly be determined likewise with the help of a time piece. For the purpose of determining the projected speed, Dr. Vettin made use of a special apparatus, a longish *camera obscura*, containing a lens which projected the image of the cloud on an inclined mirror, which in turn reflected the image on a dim glass plate at the side of the apparatus. This plate was round, and had scratched into it at its periphery a circular division, at which the movement of the cloud-image from the centre towards the periphery along a determined radius was measured. From the observed time and the inclination of the apparatus, with the help of tables calculated by Dr. Vettin, the projected speed could readily be found. Another method of measuring the height of clouds consisted in determining the angle of the last ray after sunset, or the first ray before sunrise, falling on a definite point of the cloud formed with the horizon. Besides the tables referred to in the first method described, Dr. Vettin had drawn up tables for ascertaining this angle from the observed time and for calculating the height of the observed cloud-point.—In accordance with earlier data adduced by Dr. Vettin, Prof. Boermstein showed two experiments which brought into beautiful exhibition the process by which ascending whirling currents of air were generated. A glass plate, on which stood a high glass bell, was covered with a layer of tobacco-smoke, which was heated from below by a small flame applied near the centre. At once arose an upright column of smoke, which broadened at the top and received outwards and downwards so as to form a beautiful whirl. In the second experiment a closed glass case was set on a rotatory apparatus capable of imparting to it a revolution such as the earth possessed on the northern hemisphere, or the reverse. The bottom of the glass case was warmed at a place of circumscribed area, from which arose a softly-ascending current of air analogous to that of the first experiment. If the case were now put in uniform rotation, and if, by means of a tube running through the lid down to the bottom of the case, tobacco-smoke were blown into it, so soon as the smoke came in contact with the heated place, a whirl was formed, and the smoke mounted upwards in the shape of a spiral, which, under a rotation of the case similar to that of the northern hemisphere, was in a direction opposed to the rotation of the hands of a clock. On the other hand, if the case rotated in a manner corresponding with the rotation of the southern hemisphere of the earth, the whirl of tobacco-smoke and the ascending spiral rotated in the direction of the hands of a clock. These simple and very instructive experiments may easily be performed if too much smoke be not admitted into the closed space and if the part heated at the bottom of the case be restricted to little more than a mere point.

GOLD MEDAL, INTERNATIONAL HEALTH EXHIBITION.

S. N. STOUT.

In Casks, 12/6 per 6 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 4/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.
Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—
Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.
JOHN VAN VOORST, 1, Paternoster Row.

FERNS, A SPECIALITY.

The largest and most profusely ILLUSTRATED CATALOGUE of FERNS ever published, containing much valuable information, many Synonyms, numerous Descriptions, and copious yet simple "Hints on Fern Culture"; representative of our IMMENSE STOCK of FERNS, which is probably the largest in the World, suitable for STOVE and GREENHOUSE cultivation, for OUTDOOR FERNERIES, and other purposes.

May be had on application. PRICE 1*s.*

ABRIDGED CATALOGUE OF OVER 1000 SPECIES AND VARIETIES POST FREE.

W. & J. BIRKENHEAD,
FERN NURSERY, SALE, MANCHESTER.

THE CELEBRATED

Is unrivalled for Gardeners', Foresters', Farmers', Joiners', and Amateurs' use. It requires no oil. Sharpen with a spittle or water. Puts on a keen, sharp edge; no hunting about this. Has stood the test of 100 years. Cut in Hones for Axes, Hedge Knives, Razors, Penknives, and Plane Irons, &c. Honourable Mention, Paris Exhibition, 1878; and Bronze Medal, London International Exhibition, 1884. Ask your Ironmonger or other retail house to get you one, and give my address; if he won't, drop me a post.

JOHN C. MONTGOMERIE,

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH

No. 796, Vol. 31] THURSDAY, JANUARY 29, 1885 [Price Sixpence

Registered as a Newspaper at the General Post Office]

[All Rights are Reserved

THE "LOISETTIAN"

SCHOOL OF MEMORY.

INSTANTANEOUS MEMORY!
ART of NEVER FORGETTING!!
DISCONTINUITY CURED!!

A Physiological System, wholly unlike Mnemonics, using none of its "Localities," "Keys," "Pegs," "Links," or "Associations."

Dr. ANDREW WILSON, F.R.S.E., Editor of "Health," says:—

"PROFESSOR LOISETTE'S SYSTEM IS PHYSIOLOGICAL AND SCIENTIFIC IN THE HIGHEST DEGREE."

Mr. RICHARD A. PROCTOR, Editor of "Knowledge," in No. 117, dated January 25, 1884, says:—

"I HAVE NO HESITATION IN THOROUGHLY RECOMMENDING THE SYSTEM TO ALL WHO ARE IN EARNEST IN WISHING TO TRAIN THEIR MEMORIES EFFECTIVELY, AND ARE THEREFORE WILLING TO TAKE REASONABLE PAINS TO OBTAIN SO USEFUL A RESULT."

Any Book Mastered in *One Reading.*

Great Inducements to Correspondence Classes.

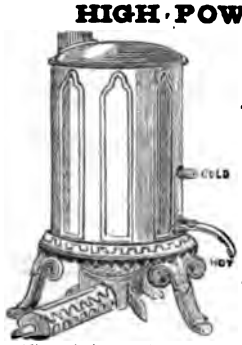
Prospectus post-free on application to

PROFESSOR LOISETTE,

37, NEW OXFORD STREET (opposite Mudie's Library), LONDON.

FLETCHER'S PATENT

HIGH-POWER, INSTANTANEOUS WATER HEATER FOR BATHS.



THE CHEAPEST AND MOST POWERFUL BATH HEATER MADE.

Small size, to heat 1 gallon per minute from 60° to 110° ... ... PRICE 50/-.

Large size, to heat 2 gallons per minute from 60° to 110° ... ... PRICE 90/-.

The Heater is strongly made of copper. The small size will provide a warm bath in 20 minutes, or with night pressure of gas in *under 15 minutes*—the large size in *half the time*. The Heater is simplicity itself, and there is nothing either to wear, or to get out of order.

TWO GOLD MEDALS

AWARDED AT THE

HEALTH EXHIBITION

For DEANE and CO.'S EXHIBIT of

Fletcher's Apparatus

The whole of FLETCHER'S Asbestos Fires, Ranges, Washers, Bath and Water Heaters, Furnaces, &c., &c., can always be seen in action in DEANE & Co.'s Show Rooms.

AS "THE BEST APPLICATION OF GAS TO HEATING AND COOKING IN DWELLINGS."

All Orders Carriage paid to nearest Station. Discount for Cash.

COMPLETE ILLUSTRATED LISTS FREE.

DEANE & CO. (46, KING WILLIAM ST.) LONDON BRIDGE.

BROWNING'S PLATYSCOPIC LENS.

Engraved Real Size.

A NEW ACHROMATIC COMBINATION,

COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge.*

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively, 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters,* 18*s.* 6*d. each power.*

Illustrated description sent free.

Sales by Auction.

A very Valuable Library of Works in Natural History, Botany, Books of Travel, and kindred subjects, Maitland and Bannatyne Club Books, and Books in General Literature, the Property of a Gentleman deceased.

MESSRS. T. CHAPMAN AND SON beg to intimate that they will SELL by AUCTION, within their Great Rooms, No. 11, Hanover Street, Edinburgh, on TUESDAY, February 10, and Two following Days, the above very select and valuable LIBRARY, embracing Rare Works on Alpine Flowers, Darwin's Works, Proctor's Works, Hooker's Works, Loudon's Encyclopædia of Plants, &c.; Flora Capensis, Flora Australiensis, Flora of North America, Prichard's Natural History of Man, Lindley's Pomologia Britannica, Lowe's Ferns—British and Exotic, Sweet's Works, The Botanical Cabinet, Morris's British Birds, Sowerby's English Botany, The Floral Cabinet, Horticultural Society Transactions, Hooker's and Seemann's Voyages, Griffith's Icones Plantarum Asiaticarum, Royle's Botany of the Himalayan Mountains, Curtis's Botanical Magazine, Edwards's Botanical Register, Hooker's Journal of Botany, Paxton's Magazine of Botany, and other serial Publications. The General Library includes Scott's Works, Britton and Brayley's Beauties of England and Wales, Swift's Works, Prescott's Works, Wellington's Despatches, Outram's Legal Lyrics, Kay's Edinburgh Portraits, Shakespeare's Works, Ruskin's Stones of Venice, &c.

As also a large number of the Publications of the Bannatyne, Maitland, Spalding, and other Clubs.

Details in Catalogues, which will be forwarded on application.

The select Collection of Minerals formed by the late WILLIAM TERRY, Esq., of Peterborough House, Fulham.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, on FRIDAY, February 6, at half-past 12 o'clock precisely, without the least reserve, the choice COLLECTION of MINERALS formed by the late WILLIAM TERRY, Esq., of Peterborough House, Fulham. The Collection consists of the very finest and most select specimens of all the rarer substances—gold, silver, and platinum, &c.; also a most valuable assortment of meteorites, with localities, and the cabinets in which they were contained. Mr. Terry spared no expense in forming this Collection, and was continually weeding out and changing specimens for any he saw better.

On view the Day prior from two till five and Morning of Sale, and Catalogues had.

Valuable Scientific Books.

Mr. J. C. STEVENS has received Instructions from the Executors to SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, on SATURDAY, February 7, at half-past 12 precisely, the valuable LIBRARY of SCIENTIFIC WORKS of the late WILLIAM TERRY, Esq., of Peterborough House, Fulham, comprising Standard Books on Chemistry, Photography, Microscopy, Mineralogy, Botany, Horticulture, &c.—Transactions of Learned Societies, including the Journal and Transactions of the Pharmaceutical Society, Journal of the Photographic Society of London, Quarterly Journal of Microscopic Science, Monthly Microscopical Journal, Sowerby's British and Exotic Mineralogy, Lavater's Physiognomonie, &c., many of them substantially bound, and all in excellent library condition.

On view after 2 o'clock the Day prior and Morning of Sale, and Catalogues had.

SILVER MEDAL AWARDED

To JAMES R. GREGORY for

EDUCATIONAL COLLECTIONS OF GEOLOGY AND MINERALOGY

By the International Health and Education Exhibition, 1884.

Medals also Awarded in 1862, 1867, 1879, and 1883 in London, Paris, Sydney, and London.

Speciality:—

GEOLOGICAL AND MINERALOGICAL COLLECTIONS

For Museums, Colleges, Schools, Lectures, Students, &c.

Catalogues and Lists on application to—

JAMES R. GREGORY,

GEOLOGIST AND MINERALOGIST,

88, CHARLOTTE STREET, FITZROY SQUARE, W.

Established 1858.

FERNS, A SPECIALITY.

The largest and most profusely **ILLUSTRATED CATALOGUE** of **FERNS** ever published, containing much valuable information, many Synonyms, numerous Descriptions, and copious yet simple "Hints on Fern Culture"; representative of our **IMMENSE STOCK** of **FERNS**, which is probably the largest in the World, suitable for **STOVE** and **GREENHOUSE** cultivation, for **OUTDOOR FERNERIES**, and other purposes.

May be had on application. *PRICE* 1*s.*

ABRIDGED CATALOGUE OF OVER 1000 SPECIES AND VARIETIES POST FREE.

W. & J. BIRKENHEAD,

FERN NURSERY, SALE, MANCHESTER.

W. SWAN SONNENSCHEIN & CO.'S LIST.

ZOOLOGY.

1. **ELEMENTARY TEXT-BOOK OF ZOOLOGY.** By Prof. W. CLAUS. Edited by ADAM SEDGWICK, M.A., Fellow and Lecturer of Trinity College, Cambridge; assisted by F. G. HEATHCOTE, B.A., Trinity College, Cambridge. With 706 New Illustrations. Demy 8vo.

SECTION 1.—General Part and Special Part—"Protozoa to Insecta." 21*s.* [*Now ready.*

SECTION 2.—Special Part—"Mollusca to Man." [*In a few days.*

Third Edition (price 6*s.*) of

2. **THE CRUISE OF THE "ALERT."** Four Years in Patagonian, Polynesian, and Mascarene Waters. By R. W. COPPINGER, M.D. (Staff Surgeon on board H.M.S. *Alert*). With 16 Full-page Plates from Sketches and Photos by the AUTHOR and Mr. F. NORTH, R.N. Demy 8vo. Cloth extra. 6*s.*

"No one could be better fitted than Dr. Coppinger to put into a readable shape the result of his investigations as a naturalist, and his impressions of strange scenery and savage men. . . . Every page attests his method and his practical familiarity, &c."—*Saturday Review.*

3. **MR. W. F. KIRBY'S ELEMENTARY** TEXT-BOOK OF ENTOMOLOGY will be ready very shortly. In medium 8vo, illustrated with several hundred Figures of British and Exotic Insects.

4. **DICTIONARY OF BRITISH BIRDS.** By Col. MONTAGUE. New Edition, by E. NEWMAN, F.L.S. Demy 8vo. Cloth. 7*s.* 6*d.*

This issue contains precisely the same matter as that in the edition of 1866, published at 12*s.*

BOTANY.

1. **ELEMENTARY TEXT-BOOK OF** BOTANY. By Profs. W. PRANTL and S. H. VINES, D.Sc., M.A., Fellow and Lecturer of Christ's College, Cambridge. Fourth Edition [1885]. *unaltered.* 275 Woodcuts. Demy 8vo. Cloth. 9*s.*

2. **FLOWERS AND FLOWER LORE.** By Rev. HILDERIC FRIEND, F.L.S. *Second (and Cheaper) Edition.* Demy 8vo. Illustrated. 10*s.* 6*d.*

"A full study of a very fascinating subject. . . . It forms a perfect treasury of curious and out-of-the-way flower 'learning.' . . . Altogether the work is an important and exhaustive one, and occupies a distinct place of its own."—*Times.*

PHYSIOGRAPHY.

1. **A BIBLIOGRAPHY, GUIDE, & INDEX** TO CLIMATE. By ALEX. RAMSAY, F.G.S. Demy 8vo. 16*s.*

"An immense list of books published during the past four centuries, notes gathered from scientific periodicals and the papers contributed to learned societies."—*Scotsman.*

2. **THE ROYAL RELIEF ATLAS OF ALL** PARTS OF THE GLOBE. By G. PHILLIPS BEVAN, F.G.S., F.S.S. Consisting of 31 "Relief" (or Embossed) Maps, with descriptive Text facing each Map. Each Map is separately framed in cardboard mounts, and the whole handsomely bound in One Volume, half Persian gilt. Royal 4to. 21*s.* [*Second Edition now ready.*

"This Atlas measures about twelve inches by ten, and is so bound as to lie perfectly flat wherever opened. . . . Every one who wishes his children to understand physical geography should buy the 'Royal Relief Atlas.' It will come as a revelation to them."—*Teacher.*

AGRICULTURE.

1. **ENSILAGE AND ITS PROSPECTS** IN ENGLISH AGRICULTURE. By J. E. THOROLD ROGERS, M.P. *Second Edition.* Illustrated. Crown 8vo. Limp Cloth. 1*s.*

2. **HANDBOOK OF AGRICULTURE.** By R. EWING. 12mo. Limp Cloth. 6*d.*

3. **HORTICULTURAL BUILDINGS:** their Construction, Heating, Interior Fittings, &c. By F. A. FAWKES 123 Woodcuts. Fcap. 4to. Cloth. 10*s.* 6*d.*

4. **RABBITS FOR EXHIBITION, PLEASURE, AND MARKET.** By R. O. EDWARDS, assisted by several eminent Breeders. 8 Plates. Crown 8vo. 2*s.* 6*d.*

[illegible] 1885

[illegible] SHIPS[1]

[illegible] By Sir E. J. Reed, [illegible] C. Griffin and Co.,

[illegible] presentation of the scien- [illegible] on the stability of ships, [illegible] a very important point— The technical nomenclature [illegible] gradually been formed in an un- [illegible] and unintelligent manner; [illegible] inconsistencies and inaccuracies. [illegible] en called by ourselves and [illegible] Edward Reed refers to the [illegible] caused by giving the name [illegible] upon two curves which are quite [illegible] One of these curves indicates [illegible] of the metacentre with draught [illegible] upright; and the other is that [illegible] ions of consecutive normals to the [illegible] hip becomes inclined from the [illegible] ves are entirely different in cha- [illegible] one point in common—viz. the [illegible] position corresponding to the [illegible] h the curve of intersections of [illegible] onstructed. The latter curve is, [illegible] of the curve of buoyancy. Sir [illegible] to call the intersections of con- [illegible] e curve of buoyancy at all angles [illegible] the upright "pro-metacentres," and [illegible] of the term "metacentre" to inde- [illegible] ations from positions of equilibrium. [illegible] bed as "pro-metacentres" are centres [illegible] curve of buoyancy. They are but of [illegible] to practical naval architects, and are [illegible] regarded by them. To persons who may [illegible] nvestigations in which such points require [illegible] with, such a term as "pro-metacentre" may [illegible] Sir Edward Reed truly says that the points in [illegible] are not 'meta-centres,' except in a very [illegible] misleading, and wholly exceptional sense." [illegible] not enter into any of the considerations by [illegible] e stability of a ship is judged of or calculated; [illegible] positions are not determined, nor even known, [illegible] ice.

[illegible] g. 2 represents the section of a ship, B B_3 the [illegible] of centres of buoyancy, and M M_3 the curve of [illegible] sections of consecutive normals to B B_3, or the evo- [illegible] of B B_3, then the points M_1, M_2, and M_3 will be the [illegible] pro-metacentres" corresponding to those angles of in- [illegible] lination at which M_1 B_1, M_2 B_2, and M_3 B_3 are respectively [illegible] vertical. M is the point corresponding to the position of equilibrium when the vessel is upright, and is the meta- centre proper. Such points as M_1, M_2, and M_3 have some- times been miscalled metacentres, and the curve M M_3 the [illegible] centric evolute. Sir E. J. Reed proposes to call [illegible] nts "pro-metacentres," and the curve M M_3 the "curve of pro-metacentres." M_1, M_2, and M_3 are centres of curvature of B B_3 at the points B_1, B_2, and B_3; and the curve M M_3 is the evolute of B B_3.

Sir Edward reminds us that the points where the lines M_1 B_1, M_2 B_2, and M_3 B_3 intersect the vertical axis of equi- librium through B, have sometimes, in this country, been called "shifting metacentres"; and he considers that although this term has a "measure of justification, its use is not very desirable, and is, indeed, likely, unless great care is taken, to introduce misconceptions into the subject." It is true that the term "shifting metacentre" was suggested for application to these points, even by so eminent an authority as the late Prof. Macquorne Rankine; but it has failed of its purpose, and passed so completely into oblivion that if Sir Edward had not re- ferred to the circumstance few of his readers would have remembered it. There is little probability of the term "shifting metacentre" now coming into use.

The most natural mode of treating these points is doubtless to class them all in the category of "meta- centres," without any qualifying adjective of a general character, such as "shifting." In France the term meta- centre includes the point M—which we regard as being the metacentre proper—and Prof. Rankine's shifting meta- centres. It is natural to regard the intersection of M_2 B_2

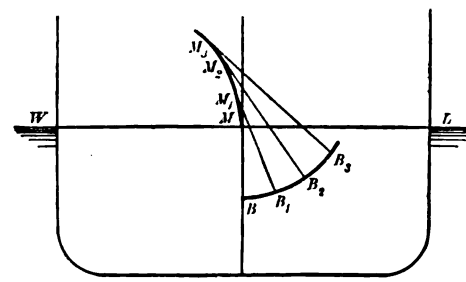

FIG. 2.

with the vertical axis of equilibrium as the metacentre for the particular angle of inclination to which M_2 B_2 relates. This is quite consistent with Bouguer's original definition of the metacentre, viz. "la terme que la hauteur du centre de gravité G, ne doit pas passer, et ne doit pas même attendre." This point constitutes the limit above which the centre of gravity cannot be raised without causing the ship to move farther away from the upright, whether the angle of inclination be great or small. It is convenient, and need not be ambiguous, to call these points meta- centres for the particular angles of heel to which they relate. Thus the intersection of M_1 B_1 with the vertical axis of equilibrium through B is the metacentre at 10° of inclination, if 10° be the angle at which M_1 B_1 is vertical; and the same for any other angle.

These points are really of importance to the naval designer, as the distance from such a point to the centre of gravity at any angle of inclination, say 30°, is equal to the length of the ship's righting lever divided by the sine of the angle of inclination. If this distance be zero the righting lever vanishes, and there will be no resistance to further inclination. If the metacentre at 30° fall below the centre of gravity the ship will tend to incline still

[1] Continued from p. 240.

able instrument, is not referred to; but the integrator which combines appliances for computing areas, moments, and moments of inertia of plane curves is described. This instrument has lately been introduced into ship-drawing offices, and is highly appreciated for the saving of time and labour which can be effected by its use, and for its comparative freedom from error. Complicated calculations can be made with this ingenious piece of mechanism by less highly-skilled draughtsmen than are required for performing the ordinary arithmetical calculations. This is a very important matter in mercantile shipyards, where the supply of scientifically-trained draughtsmen is not great. In referring to this point Sir E. J. Reed says that "in most private shipbuilding establishments these lads (drawing-office apprentices) are now required to pass an examination similar to that which candidates undergo for apprenticeship in Her Majesty's dockyards." We do not understand that this is so. It may be the case with one or two firms, but the system is a very exceptional one. Sir E. J. Reed gives a mathematical investigation of the properties of the integrator, and explains how to take off the readings for areas, moments, and moments of inertia. We notice an omission in connection with the figures given for the various constants that require to be applied as multipliers to these readings, for the purpose of converting them into actual units of measurement. The particular instrument to which the constants apply is not fully stated. The constant for areas, given as 15, and that for the area term in the expression for moment of inertia, given as 240, relate to instruments formerly supplied by M. Amsler, which had a different diameter of area wheel from those now made. We believe that the circumference of the area wheel is now 2·5 inches; so that the two constants which depend upon the size of the area wheel would, in that case, be 20 and 320, instead of 15 and 240.

The final chapters of the treatise deal with general questions relating to the rolling of ships at sea, and the effect of wind-pressure upon stability when ships are sailing among waves. The method of obtaining by experiment the vertical position of a ship's centre of gravity, and the precautions which have to be adopted in order to ensure fairly accurate results, are described.

The few omissions and defects we have pointed out are but of minor importance, and do not appreciably affect the general value of this very important treatise. It is not only the largest that has ever appeared in this country, but also the most intelligible, instructive, and complete exposition of the principles of stability. It forms a most valuable addition to the science of naval architecture, and one that has long been needed. Till now we have been unable to refer persons desirous of studying the various problems connected with the stability of ships to any work in which they would find the subject treated in a clear and comprehensive manner. Sir E. J. Reed has supplied a want that has long existed. We strongly recommend his book to all who are interested in the subject, and particularly to those whose connection with ships requires them to know upon what conditions stability depends, and how it is affected by all the various circumstances of construction and loading which may arise. Such a treatise should be especially welcome to students.

OUR BOOK SHELF

In the Lena Delta; a Narrative of the Search for Lieut.-Commander De Long and his Companions, followed by an Account of the Greely Relief Expedition and a Proposed Method of Reaching the North Pole. By G. W. Melville; Edited by G. Melville Philips. (London: Longmans and Co., 1885.)

THE sad story of the *Jeannette* Expedition has already been very fully told in the two volumes of journals left by Capt. De Long. Still, we do not object to this more detailed narrative of the experiences in the Lena Delta of those who managed to reach it, by the one most qualified to speak of them. It was by the strenuous exertions of Engineer Melville that the bodies of Capt. De Long and his companions were discovered, and that the few survivors were rescued. Concerning the physical and biological conditions of the great swamp formed about the mouths of the Lena, Mr. Melville does not tell us much more than we knew already; but his continual journeys to and from between the delta and such towns as Yakutsk, Tiumen, and others in this part of Siberia necessarily furnish us with many details of interest. As a story of remarkable adventures the book is certainly interesting. Mr. Melville's arctic enthusiasm was not in the least damped by the *Jeannette* misfortunes. Not only does he describe in the present volume his experiences as a member of the Greely Relief Expedition, but he means evidently to attempt to reach the Pole, if for no other reason but that it "may prevent other fools from going there." Mr. Melville's plan takes for granted that Franz Josef Land reaches to 85° N., which is probable enough; and he would therefore propose to utilise this as a basis of operations; around the Pole he supposes that a partial "vacuum" exists, and that partly as a consequence the ice-cap there is immovable, held in its place by the islands which he believes surround it. As to getting back when the Pole is reached, Mr. Melville believes that this could easily be effected either by Nova Zembla or Spitzbergen. Of course, the retreat would be secured by the establishment of carefully-selected depots. "Finally, I propose to prove this theory of reaching the North Pole by *going there myself.*" Every one will wish him God speed; and there can be no doubt that the best arctic authorities are agreed that the next expedition should seriously try the Franz Josef Land route.

Stanford's Compendium of Geography and Travel—Europe. By F. W. Rudler, F.G.S., and G. W. Chisholm, B.Sc. Edited by Sir Andrew C. Ramsay, LL.D., F.R.S. With Ethnological Appendix by A. H. Keane, M.A.I. (London: Stanford, 1885.)

THIS many-authored and much-edited volume is the last of the series of Stanford's well-known "Compendium," the first volume of which was issued some six years ago. That first volume dealt with Africa, and was edited, it may be remembered, by Mr. Keith Johnston, who shortly after publication lost his life attempting to explore the continent which he had so well described. There have been subsequent editions of that volume edited by Mr. E. G. Ravenstein. The succeeding volumes were South America, by Mr. H. W. Bates; Australasia, by Mr. A. R. Wallace; Asia, by Prof. Keane and Sir Richard Temple; and North America, by Drs. Hayden and Selwyn. It will thus be seen that Mr. Stanford has been fortunate in his choice of editors for the several volumes. The Compendium professes to be based on Hellwald's German work, but it may throughout be regarded as virtually original. The various editors have put so much of their own into their several volumes, and given to the whole an orientation so essentially English, that it would be difficult to tell which is Hellwald and which the "editors." In the present volume the editors and authors (or one of them, for the title-page is awkward) have wisely

retained what Hellwald says concerning the English people.

The volume is quite equal to the best of its predecessors. The physical geography of Europe occupies quite one-half, and while necessarily of the nature of a summary, seems to us carefully and accurately written. The second part of the volume is devoted to what is known as "political" geography, while Mr. Chisholm has collected into an appendix a very useful series of statistical tables. As usual we have Prof. Keane's valuable ethnological appendix, occupying some thirty pages. Though Europe is the best-known of the Continents, its ethnology is more difficult to deal with than that of any other part of the world. "Races" and languages have become so mixed up and interchanged, that it is a matter of great difficulty to distinguish between the various elements. Mr. Keane has some difficult problems to face, but probably no one is more competent to solve them. His sections on "pure races" and "mixed languages" are of special interest; he rightly concludes that in Europe we have neither the one nor the other, nor probably will they be found in any part of the world. These ethnological appendices are quite worthy of being collected and extended and published separately as a useful manual of ethnology. The maps in the present volume are many, and of much scientific value. This "Compendium" as a whole may be accepted as a really trustworthy and manageable geographical reference-book.

Nine Years in Nipon; Sketches of Japanese Life and Manners. By Henry Faulds, L.F.P.S. (London: Alexander Gardner, 1885.)

THE author of this beautiful and entertaining volume is a missionary doctor who, in the course of his nine years' residence in Japan, has, as he tells us, mixed with every class in the country except the very highest. He has visited most of the usual sights, such as Fuji, Nikko, and the inland sea, but otherwise his professional duties appear to have kept him very close to Tokio. To make up for this he has seen the lower and middle classes of Japan as few other Europeans have had the opportunity of seeing them, and after all he is able to say that the land is not all barren. He stands up bravely against the redoubtable Miss Bird for the much-maligned morality of the Japanese people. He thinks that brilliant lady's dictum that the nation is sunk in immorality extremely harsh and erroneous. The recent intellectual progress of the Japanese is, he believes, very striking, though not as yet so general as many have supposed; their political progress is unprecedented, but he thinks that on the whole the moral elevation of the mass of the people within the last decade has been still more striking and noteworthy. A considerable portion of the volume is made up of bright, lively sketches of scenes by the way in Tokio, and along the roads in the interior. These are very well done, but they might almost be equally well done by an ordinary tourist with some literary gifts and graces. It is in the last half of the volume that we come on the real student and acute observer of Japan. It is only an old resident, whose familiarity with the everyday sights and sounds around him had never blunted his original sense of their picturesqueness and strangeness, that could have written the chapters on the Japanese philosophy of flowers, Japanese art in relation to nature, and how the Japanese amuse themselves. In connection with the universal spread of education throughout Japan (the author can only recall one or two clear instances in his experience of Japanese people being unable to read or write), he makes an observation which we do not remember to have seen or heard before, viz. that the cause is Buddhism. The effect of what he calls the new and genial enthusiasm of humanity, which came from India, taught everywhere the unity and brotherhood of man, and so literature could no longer be maintained as the peculiar possession of any caste of mere priests or princes. "My Garden and its Guests" is a delightful chapter of popular natural history. In an introductory chapter, in which he surveys the canvas on which he is about to draw his sketches, he has a few words to say on the ethnology of the Japanese. He says that the Ainos, "in spite of a great deal of crude writing on the subject" (to which, it should be stated, Mr. Faulds has added his mite, though not in this book), cannot show any claim to be considered the aborigines; they are not necessarily older in their occupancy than the Japanese themselves. This heterodox statement is thrown off with a *nonchalant* air, as of one making a common matter-of-fact observation; but it would be interesting to know the author's grounds for it. The shell-heaps (to take only a single instance) which have been found near Tokio, and even farther south, and which resemble in every respect heaps formed, or in process of formation, outside Aino villages in Yezo, form a strong argument the other way; we were under the impression, also, that history told us of the existence of Ainos on the spot on which Ota Dokan built himself the fort which afterwards grew into Yedo in the fifteenth century. But it seems waste of time to refer to such matters in the case of a man who has the hardihood to confess that he does not know exactly what a Mongol is, and that he thinks it only deepens our ignorance immensely to call another race Mongoloid. To make up for this, however, and by way of washing his hands clear of the matter, he gives all the original theories by which science, aided by tradition, accounts for the original migration of the Japanese people. As there are six points of the compass (zenith and nadir being added) in far-eastern cosmography, so there are theories of migration from each one of these six points:—(1) the soul (Buddhist view); (2) America; (3) China, or Accadia; (4) Africa, or the Malay Peninsula, or the Southern Isles of the Pacific; (5) Saghalin, or Kamtschatka; (6) the celestial regions of the Sun; with which comprehensive category Mr. Faulds takes leave of ethnology. For the rest, the book is as charming in all externals as in its contents. It should take its place in the front rank among popular books on Japan; indeed, since Mitford's "Tales of Old Japan," we cannot recall a more interesting volume on the country, or one which should be more read in England.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Krakatoa

By the return from the Caroline Islands, on the 25th inst., of the *Jennie Walker*, I am enabled to supply a few additional details about the westward progress of the equatorial smoke-stream from Krakatoa in September 1883. In NATURE, October 2 (p. 537), is my extract from Miss Catheart's journal describing the obscuration of the sun at Kusaie, or Strong's Island, on September 7, 1883. The Rev. Dr. Pease and wife came as passengers by the *Jennie Walker*. They state that, while they were dressing their children on the morning of September 7, the natives came anxiously asking what was the matter with the sun, which rose over the mountains with a strange aspect. It was cloudless, but pale, so as to be stared at freely. Its colour Dr. Pease called a sickly greenish-blue, as if plague-stricken. Mrs. Pease's journal described it as "of a bird's-egg blue, softened as this colour would be by a thin gauze." Around the sun the sky was of a silvery gray. At the altitude of 45° the sun appeared of its usual brightness, but resumed its pallid green aspect as it declined in the west.

On the 8th the sun appeared as usual. They did not notice the red glares until some days after.

Strong's Island is in lat. 5° 20′ N., long. 163° 10′ E. Their 7th is our 6th, one day later than the tremendous display of colours in the Honolulu skies on September 5.

Dr. Pease reports a considerable drift of pumice-stone landed for several months past upon the *west* shore of Kusaie. Many pieces are from twelve to sixteen inches thick, and loaded with barnacles. I have now before me a piece of pumice presented by Dr. Pease, with small barnacles attached. Dr. Pease also reports many large trees landed there of late. They are up to five feet in diameter, with huge buttressing roots, much pumice jammed in the roots, their wood as light as cork. This species of tree is unknown in Micronesia. Are these corky trees, as well as the pumice, part of the wreckage of Krakatoa? Dr. Pease states that this year, as happened once before, the prevailing westerly current has been exchanged for one running easterly. Drift-logs of redwood from California frequently land on Kusaie, as they do here.

On the passage hither between Kusaie and Jaluit Dr. Pease saw large tracts of floating pumice in a comminuted state. The Rev. E. T. Doane of Ponape (lat. 6° 47′ N., long. 158° 20′ E.) writes me that large quantities of pumice are floating around that island. Capt. Holland, of the *Jennie Walker*, states that all the way between Jaluit and Ruk or Hogolen, some 1500 miles, he encountered vast tracts of pumice. Many pieces were as large as hats. He met five or six large trees in the same regions. One with its branches was mistaken for a boat. This association of floating trees with pumice seems very suggestive of Krakatoa, especially as all have been long floating in the sea.

I send herewith a small slab of the pumice from Strong's Island, hoping that you will have it compared with known Krakatoa ejecta.

During the past month of December the sky-glows have doubled in brightness. A like augmentation of brilliancy took place at the same period in 1883, as reported by me in your columns. Permit the suggestion that the winter cold enlarges the concretions of ice around the dust-nuclei in the upper atmosphere, thereby multiplying their reflecting power. I see no reason to believe that any addition has been made to the original diffusion of dust from Krakatoa. The whitish corona which first appeared around the sun in September, 1883, has always and continuously been conspicuous since that time. It is one and the same continuous phenomenon which began here with that tremendous dust-cloud of September 5, 1883.

Recent Earthquakes

EN relation possible, mais non probable, avec les tremblements de terre d'Espagne j'ai à vous signaler les secousses suivantes observées en Suisse :—

25 décembre, 1884—à Zernetz, Engadine, secousses à 8h. 17′ S., et 11h. S., heure de Berne.

(8h. 17′ heure de Berne correspond à 7h. 32′ heure de Madrid. La première de ces secousses a donc eu lieu 20m. avant la grande secousse de Grenade du 25 déc. à 8h. 52′ soir.)

1 janvier, 1885—2h. matin, légère secousse, signalée à Lausanne par un seul observateur.

21 janvier, 1885—Entre oh. et 1h. matin, secousse à Ennenda, canton de Glarus.

Dans les Alpes françaises.

le 5 janvier, 1885, à 3h. matin à Chambéry (Savoie).

" " à 5h. 50′ matin à Embrun (Hautes Alpes).

Agréez, Monsieur, l'expression de mes sentiments très distingués.

F. A. FOREL

Morges, 24 janvier

ON Thursday evening last, at a time which is variously stated from 8.30 p.m. to shortly before 9, a rumbling noise, accompanied by a sensible trembling of the earth, and in some instances by a slight "rocking" of cottages, was heard and felt over several parishes in this neighbourhood. I have already had independent testimony of it from West Buckland, Bradford, Nymhead, and Langford, in a line from north-west to south-east across the upper part of the Vale of Taunton. Some observers state that the noise and motion seemed to come from the north-west. There can be but little doubt but that this was a slight shock of an earthquake. It would be interesting to know whether anything of the same kind had been observed elsewhere at the same time.

Nymhead Court, Wellington, Somerset, January 24

The Lexden Earthquake

THE earthquake alleged to have taken place near Colchester on Sunday night, Jan. 18, and mentioned in the "Notes" of NATURE last week, on the authority of the *Standard* newspaper, turns out on inquiry to have been reported on very doubtful authority. The place referred to as "Leden" is evidently meant for Lexden, which is really a suburb of Colchester. Immediately after seeing the newspaper paragraph I communicated with some of the residents, asking them to obtain particulars for me, as the occurrence of another shock so near the district which was skaken in April of last year, would have been of considerable interest in connection with the report upon this last earthquake, which I am about to present to the Essex Field Club. It seems, however, according to the results of these inquiries, confirmed by a paragraph in the *Colchester Gazette* of January 21, that the shock was said to have been felt by one person only, the postman, and nobody else in the place heard or felt anything, nor was any crockery shaken or any vibration experienced in any other house. One gentleman, who was out of doors at the time mentioned (midnight), states that he heard a peal of thunder, but felt no shock, and he suggests that this might have awakened the postman, upon whose authority the newspaper paragraph appears to have been founded.

The statement that the shock was felt at Aldeburgh rests also on the authority of one person only, and it shows with what caution such statements should be received in the absence of instrumental records.

Barrenness of the Pampas

MR. EDWIN CLARK overlooks, I think, an important factor in the present treeless condition of the Pampas (of the La Plata, so far as my own knowledge extends only), and of the difficulty of establishing trees on those plains. North of Monte Video, for some hundreds of miles, the leaf-eating ant is omnipresent. I have seen streams of them running along the beaten paths to their nests, each ant carrying the yellow petals of some plant similar to the buttercup. When I first noticed, from my horse, this procession of golden leaves, I was greatly astonished. Familiarity, however, soon dispelled this. The *opima spolia* was being carried to their nests and taken under ground, no doubt as a provision for the winter. The ants were about a quarter of an inch in length, and of a beautiful steel-blue colour. Those I picked up for examination demonstrated their powers by shearing off the hard cuticle of my thumb or fore-finger with their mandibles. Subsequently, I made the acquaintance of a gentleman, well known in the Banda Oriental, the owner of the "Estancia Sherenden." He showed me a splendid grove of about two acres of *Eucalypti* of several species—the "blue" and "red" gum chiefly. These he had reared from seed, their enemies being these ants. As soon as the first leaves of his cherished plants appeared, the ants cut them off. He then got a drum of gas-tar sent up from town, and made a circle round each plant. The ants objected to this, and all the trees made a start. For three years in succession he carefully painted the stems with tar, and eventually they got so far away as to be able to supply the wants of their foes and still flourish. When I saw these trees they bore finer foliage than I ever met with in the Australian bush during four years' experience. They were then eight years old. Many were forty feet high, and thirty-six inches round at some three feet from the earth.

I think none of the animals mentioned by Mr. Clarke, *certainly not any of the rodents* in his list, would be likely to touch gum trees, and the repugnance to them of sheep, oxen, and horses in Australia is well known.

Maize grows freely in the Banda, but it grows too fast for these ants to destroy it. The attacks of those from nests within marching distance are powerless on an acre of Indian corn.

When I examined the *Eucalypti* at "Sherenden," many ants were coming down the trees with cuttings of the leaves in their mandibles.

If you will allow me a word of suggestion in addition, I would say to every one who establishes trees on the Pampas

Seek out the nests of these ants within a quarter of a mile (that would be enough), light a good fire over them in winter, when the inhabitants are at home, and after that there would be no difficulty in gradually covering the ground with plantations. The dried stems of the ubiquitous thistle, cow-dung, corn-cobs, or "paja" grass, would burn out these pests.

ARTHUR NICOLS

Cross-Breeding Potatoes

IN the interesting account of the latest successful attempt at raising hybrid potatoes by crossing with different species instead of, as heretofore, by varieties, it is taken for granted the new production will be disease-resisting. Until, however, time has tested the powers of the plant after cultivation, stimulated with all the appliances the potato-growers have at their command, it is rather premature to trust to this. Forty years ago I saw potatoes growing from seed imported direct from South America, and after three years' cultivation they all went with disease in the year 1848. The species I could not tell. The same varieties which go off with disease in this country are never affected in Tasmania, Australia, or New Zealand. At present the newer sorts in cultivation grow so sound and healthy that champions of fine quality over all the east of Scotland are now offering wholesale at three pounds for one halfpenny, and cannot find buyers. The results of the experiments in crossing referred to, while most interesting, will only prove beneficial if a disease-resisting plant is produced having all the table qualities of the old Regent, as well as its great reproductive power, which, with its ability to resist disease, it has now lost.

JAMES MELVIN

43, Drumsheugh Gardens, Edinburgh, January 19

PROTOPLASM[1]

THE fact of a direct continuity between the protoplasmic contents of adjacent cells is an important factor in plant histology. The history of this subject is briefly as follows:—

The individuality of the plant-cells, defended by Schleiden,[2] was first criticised by Hofmeister,[3] and more positively and later by Sachs.[4] For Sachs and also for Strasburger[5] the plant is only one cohering protoplasmic entity. Nägeli[6] has also in a recent work supposed that the protoplasm of each cell is in direct communication with that of the others, by means of delicate protoplasmic filaments.

So far the theoretical side of the question. The first *direct* observation was made in the year 1854 by Theodor Hartig, and not by Sachs as Walter Gardiner[7] states. We find in Hartig's paper the following description of the continuity of sieve-tubes, "Behandelt man in Wasser macerirte Siebröhren mit Schwefelsäure, so erfolgt häufig eine völlige oder theilweise Trennung der beiden Endflächen, in welchem Falle genau zwischen den correspondirenden Ptychodearmen sich Fäden *ausziehen*, die durch Tod dieselbe Färbung und Structur zeigen wie die Ptychodearme selbst. Fig. 18 stellt einen solchen Fall dar."

After Hartig's discovery, confirmed later by Hanstein and Sachs: Mohl, Nägeli, De Bary, Dippel, Wilhelm, Tauczewski, Russow, &c., examined the sieve-tubes and their plasmic connection. For a long time the connection of the sieve-tubes remained the only known fact, until Bornet[1] and E. Perceval Wright[2] in 1878, J. G. Agardh[3] in 1879, and Schmitz[4] in 1883 (the connective filaments were seen), and further, in 1884, Th. Hick[5] and Kolderup-Rosenvinge[6] published some accounts of the communication between adjacent cells in the Florideæ. It seemed to me very probable that in the Cyanophyceæ also communications between the adjacent filament-cells would be found. At least the drawings that Wille[7] gives put one in mind of similar phenomena.

After J. G. Agardh,[8] Tangl,[9] in 1880, succeeded in proving the direct communication in phanerogamous plants between the endosperm cells. In the various papers of Russow,[10] Gardiner,[11] and Hillhouse,[12] these communications are stated in many cases to occur in the bast-parenchyma, the phloem-ray cells of numerous plants, in various pulvini, in the cells of the leaf of Dionæa, in the cells of the stamens of Berberis, in a great number of endosperm cells, and in various cortical tissues.

Finally, Terletzki[13] gave a brief account of the plasmic communication of the parenchyma-cells in the stem of some ferns. I have published also myself[14] a brief account of this interesting object, and described briefly the observations made during the summer of the past year. After Terletzki's paper I was induced to publish my observations, with the full details.[15] The physiological significance of the communication was, in the first instance, not understood; it was believed to be chiefly for the conduction of stimulus in the sensitive organs. But, after numerous observations, there was little doubt that the occurrence of communications between neighbouring protoplasts is not the exclusive privilege of the sensitive organs, and I further claimed the universality of the communication (at least in tissues) in my first paper.[16] This universal occurrence is since confirmed by recent researches.

I have in my second paper[17] given the results of my investigations made on various vegetative tissues. It is superfluous to say anything of the importance of the methods employed in such investigations. For fixing

the freshly-collected materials I used alcohol, osmic or picric acid; all the observations described below were made upon fresh material, treated, after fixing for a few minutes, with strong or dilute sulphuric acid, so as to swell the cell-walls.[1] The fresh material was first cut in alcohol (or osmic or picric acid); the sections were then for a short time placed in a drop of sulphuric acid, and washed rapidly in a watch-glass with distilled water. After washings in several watch-glasses, the sections may be stained. For staining I first used the saffranine, and later solely the eosine (from Dr. Th. Schuchardt, Görlitz, Silesia). The eosine has a great and admirably defined selective staining power. It is a very excellent negative reagent for the cell-wall, and when employed with some precautions colours only or almost only the protoplasm. It is however requisite that a dilute solution of the dye should be made (1 part of eosine to 50-60 parts of water), and that the stained sections should be washed carefully (for ten to fifteen minutes) in water.

That the phenomena detailed below are not artificially produced by reagents is proved in certain instances. The presence of the connecting protoplasmic filaments in the *intact* (not swollen) *normal cell-wall or pit-closing membrane* was witnessed in the medullary cells of the mistletoe, the sections of which were merely mounted in water and stained with eosine.

I now proceed to give an account of the results I obtained with the various tissues in which the continuity of protoplasm was shown to exist.

Epidermis. Glaucium Fischeri gave the first results. In the leaf-epidermis the connecting processes of the protoplasms, many in number (one for each pit), are well defined; the same is the case in that of Viscum and Loranthus, but in the latter plants the fine connecting-threads were also visible. From the protoplasms of the epidermis-cells radiate numerous processes towards the pits, and in any two neighbouring cells the processes from the one protoplast are exactly opposite those proceeding from the other. *All the epidermis-cells*, as in *Ficus elastica*, are in direct communication with one another and with the "guard-cells" of the stomata. The same is also the case *in epidermis composed of several layers*. The connection is very difficult to make out, though visible after a moderate swelling in the *collenchymatic-hypoderm* (Rhus, Cotinus, *Cucurbita pepo*, Solanum, Liriodendron, &c.).

The *bark-parenchyma* is one of the most favourable objects for investigation, and even when the cell-wall has been very conspicuously swollen or dissolved, the connection is unaltered (Loranthus, Viscum, *Abies alba*, *Picea excelsa*, *Gingko biloba*, &c.). When no *hypoderm* exists, the protoplasts of the epidermic-cells should be directly connected with those of the bark-cells. Such is the case in Viscum and Loranthus. The epidermal cell-walls of these plants may have undergone considerable swelling, and so the connective processes become very extended, but the fine connective threads are still conserved. In the *leaf-parenchyma* (Viscum, Loranthus) the connection is very distinct also in the cotyledons of *Phaseolus multiflorus*. It is very difficult to prove the communication in leaves where the parenchyma has been doubly differentiated, viz. into chlorenchyma and into pneumo-enchyma. The *medullary-parenchyma* of Loranthus or Viscum furnish excellent objects for such investigations; the fine bent threads (five to eight in number) can be very *distinctly examined* after a feeble swelling of the cell-wall. In the Coniferæ I find only the connective processes distinct (Gingko, &c.). In the Loranthaceæ the communication is to be directly seen between the *medullary-ray-cells* and *xylem-cells*, between the *phloem-ray-cells* and *bast-parenchyma*; finally between the *medullary-ray-cells* and the *sclerenchyma-cells* [these last are found in the neighbourhood of the xylem (primary) vessels in Viscum.]

The *bast-fibres* of Viscum, Loranthus, are in direct communication with one another, and in Viscum the fibres of the inner-phloem also communicate with the medullary-cells. The communication between *cambium*, *young bast-fibres*, and *bast-parenchyma*, in the Coniferæ can be demonstrated only with high powers. The communication and connection of the *soft-bast* protoplasts is eminently remarkable. These protoplasts remain in connection even after total dissolution of their cell-walls (Cucurbita, Coniferæ, Loranthaceæ, &c.). I investigated also the sieve-tubes, and have found that these in their entire length are connected with *neighbouring sieve-tubes*, or *bast-parenchyma-cells*, or *collateral cells* (*Nebenzellen*) (Viscum, Loranthus, *Ficus elastica*, &c.). The connective threads are often strongly developed in Cucurbita. They assume the figure of a compressed sphere.

Xylem.—I may remark that the details of the xylem communications are very difficult to observe. In general I have studied the communication of the xylem elements best in the Loranthaceæ, and especially in Viscum. The xylem of the mistletoe is composed of libriform cells, compensating cells (*Ersatzzellen*), and vessels. The cell-walls of the libriform cells are very much thickened, and bear pits only on the middle part of the cell. These cells are variously curved and bent, and offer favourable conditions for investigation—but then the communication of the *libriform cells with one another*, *libriform cells + compensating cells*, and of the latter together can be easily seen. In the Coniferæ the communication of the xylem elements is only clear in the younger states. In the *young tracheides* the distinct threads could be very clearly seen. In the *older tracheides* merely a striation (caused by the threads) could be detected through the pit-closing membrane). As regards the occurrence of a direct continuity, the *xylem vessels* gave generally a negative result. Although in many instances the occurrence of protoplasm in the great xylem vessels could be demonstrated, still direct communications seemed to me to be extremely rare. I could find this direct connection in one instance in Loranthus. The great (but only the pitted) vessels were here connected with the adjacent cells.

Finally, the protoplasts of the secretory cells are also in direct communication with the neighbouring protoplasts, such as in the resin-cannel cells. The cells of the resin-cannels are, in the Coniferæ, directly connected with the adjacent leaf- or bark-parenchyma, or phyllogen-cells. In the bark of Gingko I was also able to confirm the communication of the crystal-bearing cells (crystal-glands) with the bark-parenchyma cells. I have no doubt that the same structure would be equally well demonstrated in the various secretive cells and vessels. In all the observed cases the communication of adjacent protoplasts is effected by delicate wavy protoplasmic threads. The connective thread either in a round-about way traverses the sieve-pore pit-closing membrane, or directly traverses the cell-wall when the membrane is unpitted or the pits feebly developed. From a physiological point of view the pits form one of the most important arrangements.

The protoplasts are also in direct connection with the intercellular protoplasm. The intercellular plasm which fills the intercellular spaces was first observed by J. G. Agardh[1] in the Florideæ, and by Russow[2] (1882) in various phanerogamous plants. I have (1883) also studied (first in the bark of *Liriodendron tulipifera*) its occurrence in many phanerogamous plants, and published my observations in 1884.[3] At this time also Berthold published a paper[4] in which he confirmed its occurrence

[1] See, for details of my method, *Zeitschrift für wissensch. Mikroskopie*, &c., i. ii. p. 301, 1884.

[1] *L. c.*, p. 140 &c. [2] *L.c.*, p. 350 &c.

[3] In the *Magyar Növénytani Lapok*, viii. 1884, pp. 19, 74.

in many plants, and later Terletzki[1] gave some details. The observations of these authors established the occurrence of protoplasm between the parenchyma cells in a small number of plants, but as I have stated this is not a rare phenomenon, but one of general occurrence, and I have found that the intercellular spaces of the true prosenchymatic tissues may also contain protoplasm.

I have investigated the plasma of the intercellular spaces in various collenchymatic, parenchymatic, and prosenchymatic tissues. For the investigation it is very important to use the reagents (absolute alcohol, picric acid, or osmic acid) very shortly before cutting the sections. Between the larenchyma cells, in the intercellular spaces protoplasm will always be found (bark and medullary parenchyma of the Loranthaceæ, Gingko, &c.). In longitudinal sections made of thick (2½ cm.) branches of Viscum the connection between the medullary parenchyma cells and the protoplasm filling the intercellular spaces is also clearly to be seen. On the contrary, between the thin-walled cells which contain little protoplasm the intercellular plasm cannot, or in very rare instances, be detected (medulla of Phaseolus, Cucurbita, Sambucus, &c.). In the prosenchymatous tissues, *e.g.* in the bast-fibre of Viscum—after moderate swelling with sulphuric acid—the intercellular protoplasm, when stained with eosine, is clearly to be observed. The connection of this intercellular protoplasm with the protoplasts of the fibres is easily seen. We find intercellular protoplasm also in the xylem, *e.g.* in *Rhus cotinus*.

Most important is a fact which I have discovered in the course of my investigations, namely, the occurrence of inter-lamellar protoplasm. This was present very constantly in the leaves of mistletoe. The sections prepared with dilute sulphuric acid and stained, very exactly showed the fine plasmatic threads, corresponding in their disposition exactly to the middle lamella. This middle-lamellary "protoplasm" surrounded the protoplasts as a frame the picture, and ended in the protoplasm of the intercellular spaces. The threads are thicker at these points. The greatest precautions must be taken in the investigation of this middle-lamellary plasma; all very strong acids, &c., should be kept away from the prepared sections. When the cell-wall is very vigorously swelled the fine processes which bind the protoplasts together appear penetrating into the plasma-frame. This plasma-frame surrounds each cell, and in a section the framework of lamellæ occur in all planes and in all successive sections, and all the various constituent threads appear to intersect one another at all angles; it is consequently clear that the middle-lamellary plasm forms a *plasmatic mantle* round the protoplasts which is increased at each edge with the pillar-form (of three to four sides) intercellular plasm portions.

The intercellular plasm preserves its vitality, and in some instances we observe that some changes take place in the intercellular spaces. The intercellular plasm may be observed to cover itself with a special cell-wall; this membrane is the product of the intercellular plasm. This protoplasm can transform itself into a true new cell. In many cases in various tissues we have found this new mode of cell-formation, thus in the collenchymatous tissues (hypoderm of Liriodendron, Ficus, Sambucus, Solanum, Cucurbita, &c.), or in the xylem (*Rhus cotinus*), in the common parenchymatous bark (Viscum, Loranthus, &c.), in the medulla, &c. These newly formed cells grow very fast, and are only in their form and appearance different from the older cells. This cell-formation is very rapid, and it appears at first sight that the number of the tissue elements is by these "intercellular cells" (*Interstitialzeller* of J. G. Agardh,[2] who has observed this metamorphosis in the Florideæ), or "between-cells" (*Közti sejtek* in Hungarian), considerably increased. A consequence of this great and fast growth is the formation of new "secondary" or "tertiary" intercellular spaces round the newly formed or transformed cells.

General Results.—I will now briefly conclude with a statement of the general results of my investigations upon the communication of the protoplasts, and upon the intercellular and middle-lamellary plasm.

(1) The protoplasts of all the tissues in united cells are in direct connection by means of finely attenuated protoplasmic threads.

(2) The connective threads traverse the pit-closing membrane (which is of a sieve-plate structure), while in unpitted cells they traverse directly the cell-wall. By these threads is the communication between the connective processes which occupy the pit-cavity from both sides directly established.[3]

(3) The intercellular plasm occurs not only in the intercellular spaces of the parenchymatic tissues, but also in those of true parenchymatic tissues.

(4) This intercellular plasm contains, in many cases, chlorophyll-granules[4] (Viscum).

(5) The intercellular plasm is in direct connection with the adjacent protoplasts.

(6) Corresponding to the middle lamella around the cells, we find a plasmatic frame; the sides of this frame end in the "intercellular" plasma. This plasmatic frame forms a veritable mantle round the protoplasts, and is increased at each edge by an intercellular plasm portion, which latter has a pillar form.

(7) The connective threads of the protoplasts traverse this "middle-lamellary" plasma; both are also connected.

(8) The probable origin of the intercellular plasma is this. During the cell-division, when the division was almost ended, little cytoplasmic portions become included in the young cell-wall, and it is also very probable that the connective threads, in many instances, are the remainder of the "nuclear connective threads," and that the middle-lamellary protoplasm is the remainder of the "cell-plate." All these plasma portions are by the thickened cell-wall much compressed together, and therefore only visible or distinctly visible by the swelling of the cell-wall.

(9) The intercellular plasm can cover itself with a cell-membrane, and in this way we find at the place of the intercellular spaces veritable new cells. About these new cells appears later new secondary or tertiary intercellular spaces.

(10) The protoplasm of the crystal-bearing cells (crystal glands) and that of the resin-cannel cells is also in communication with the adjacent cells.

The protoplasts of the plants (composed from tissues) form a higher unity, one synplast.

COLLECTING DESMIDS

IN his recently published "Desmids of the United States" the Rev. T. Wolle gives the following directions for collecting Desmids:—

The outfit need not consist of more than a nest of four or five tin cans (tomato or fruit), one within the other, for convenience of carriage, ten or twelve wide-mouthed vials, and a small ring-net made of fine muslin at the end of a rod about four feet in length. After selecting what seems to be a good locality, drag the net a few feet among the grasses and mosses, allow the bulk of the water to drain through the muslin, and then empty the residue into one of the cans; repeat this process as often as may be desirable. Ten or fifteen minutes after the cans have been filled most of the surface-water may be poured off, and the remainder transferred to a glass vial, where the solid contents will gradually sink, and the superfluous water can be again poured off, and the vessel

[1] *l. c.*, p. 169. [2] *Botaniska Notiser*, 1884, p. 130.

[3] Gardiner has also observed this fact in the plants investigated by him; for this reason we give this in the first place.

[4] J. G. Agardh has also observed endochrome granules in the intercellular spaces of the Florideæ. See *Botaniska Notiser*, 1884, p. 105.

filled up with deposits from other vials. In shallow places *Sphagnum*, *Utricularia*, *Myriophyllum*, or other finely cut-leaved water-plants should be lifted in the hand, and the water drained or squeezed from them into a tin can, to be subsequently treated in the same way. A few drops of carbolic acid in each vial, just enough to make its presence perceptible, will preserve the contents for months, and even years, from deterioration; the chlorophyll may fade, but this, in the case of Desmids, is of little importance; nevertheless, when practicable, always examine the materials when fresh. When dried on paper for the herbarium, the specimen can still, after being moistened with water, be examined under the microscope, but not with the best results, since the drying up is apt to collapse or otherwise distort the cells.

The collector will not know the value of his find until it has been brought, drop by drop, under the microscope; and out of the entire mass he may discern nothing to reward his labours. This, however, should not discourage him, as one or two failures are to be expected before meeting with an adequate reward. Sketches ought to be made, which should, of course, be very exact; and for this purpose the microscope should be provided with an eye-piece micrometer. It is so difficult to separate Desmids from their accompanying foreign matters, that it is seldom amateurs can mount them satisfactorily on slides; and this method of preserving specimens cannot therefore be recommended.

RELATIVE FREQUENCY OF STORMS IN THE NORTHERN HEMISPHERE[1]

THE portion of the northern hemisphere selected by the Signal Office of the United States for this discussion is necessarily that part for which the data required are available, and it may be considered as comprising a broad belt of from 30° to 40° of latitude in width, extending from the Pacific sea-board of America, through the United States, Canada, the Atlantic, and Europe, with the North of Africa, eastward into Western Siberia. It thus embraces some of the more important regions of the globe, including the great routes of commerce across the Atlantic. The thirteen charts, which show graphically the relative storm frequency for each month and for the year, have been constructed from data referring to 134 months in all, extending from 1863 to 1883. Of the storms which occurred in this extensive region from January 1876 to August 1881, the history of 2730 is briefly summarised. Of these 413 began and ended in America; 589 began in America and ended in the Atlantic; 190 began in America and crossed the Atlantic; 326 began and ended in the Atlantic; 655 began in the Atlantic and ended in Europe; 491 began and ended in Europe; and 66 began in America and crossed the Atlantic and Europe. The important bearing of these facts on the telegraphing from America of forecasts of storms about to strike the coasts of Europe scarcely needs to be referred to further than to remark how essential it is for the usefulness of such a service that it be placed in the hands of some competent and responsible central authority in the United States, as was suggested by us in 1879 (NATURE, vol. xx. p. 359), and which, we believe, has been carried out.

The chart for the year shows that the region where storms occur with greatest frequency is a long belt in America of about 200 miles in width, extending from the head waters of the Red River, about 95° W. long., eastwards through the Great Lakes to the mouth of the St. Lawrence, about 70° W. long. Surrounding this is a more extensive region where the number of storms, though not so large, is still a good way above the average; and again, surrounding this latter, is a still wider region, stretching from 105° W. long. eastward through the States and Canada, and through the Atlantic as far as 20° long. W. This is one of the most important regions of the globe as regards storms or cyclones. The excessive frequency of storms is probably due to a prevalence, during a large portion of the year, of the south-east trades, with a continuation of easterly and southerly winds into and through the Caribbean Sea and Gulf of Mexico, by which, from the superabundant vapour thus poured northward and eastward over the United States by upper and lower currents, frequent storms are originated.

Another region of considerable storm frequency extends from the south of Greenland, through Iceland and Farö, to the north of Sweden. Over this region it may be assumed that a more extended and exhaustive discussion of the storms occurring there than it has been possible to make, will reveal a greater frequency than is indicated on the chart, a supposition rendered highly probable by the frequent and extensive fluctuations of the barometer which occur in Iceland during at least three of the four seasons of the year. Of great interest is the less frequency of storms in the Spanish Peninsula and northeastwards, through Central Europe, as far as Berlin; and the increased frequency to the southward over the northern half of the Mediterranean and the Black Sea, pointing to the important *rôle* played in the storms of that region by the evaporation from these seas.

This is substantially the distribution of frequency during the colder months of the year, when the larger number of storms occur. In the spring and summer months the distribution is materially altered. Thus, in April the regions of greater frequency extend further to southward in the United States and the Atlantic. It is in Europe, however, where this southing of the tracks of cyclones is most decidedly marked. At this season a broad patch is seen to overspread Ireland and England, and extend thence southward over the north of Spain, and then eastwards over nearly the whole of the south slope of Europe to near the Caspian Sea. As directly connected with the greater prevalence in spring of cyclones in Southern Europe are the east winds, which acquire at this same season their greatest virulence over the north-western part of the Continent. In summer, on the other hand, the coloured patches marking the regions of greater storm-frequency lie further to the northward than at any other season. Thus, in August, immediately to the north of 50° N. lat., there is an extensive region of greater storm-frequency, of about 900 miles in breadth, extending from about 45° W. long. to eastward as far as St. Petersburg. In this season the south of Europe is practically rainless, and storms are of extremely rare occurrence.

From the charts, the tracks usually taken by storms in different parts of the wide region under review cannot be ascertained, but can only be guessed at inferentially. It would be a great improvement if, in subsequent issues of the paper, these tracks were entered on the charts. This was done in 1882 in the "Physical Atlas of the Atlantic Ocean," prepared under the direction of Dr. Neumayer, of Hamburg. It was there shown from centres of the most frequent occurrence of low barometers, that to the west of the Mississippi is the region where most of the United States storms originate; that many of the Atlantic storms have their origin in the Gulf of St. Law[illegible] and that the storms of North-Western Europe [illegible] originate in mid-Atlantic and to the south-west [illegible] land. The centres of low pressure also point[illegible] retardation in the onward course of storms on ad[illegible] on large masses of land, as happens when sto[illegible] proach the south of Greenland, the south of the Islands, Denmark, and the Lofoten Isles. Of all tracks approximately known in the northern hemis-

[1] Charts of Relative Storm Frequency for a Portion of the Northern Hemisphere. Prepared, under the direction of General W. B. Hazen, Chief Signal Officer of the Army, by John P. Finley, Sergeant, Signal Corps, U.S.A. (Washington: Signal Office, 1884.)

the most frequently taken is that by the storms of the United States, which pursue an easterly course through the lakes to the Gulf of St. Lawrence. A considerable number advance from Nova Scotia to Davis Straits, but the greater number take a north-easterly course through the Atlantic towards Iceland and the North Cape. Among other tracks less frequently followed, but of great importance commercially and otherwise, are these: from New Orleans, along the east coast of the United States, towards Nova Scotia; from mid-Atlantic to the south of Ireland, and thence through Europe to the northern shore of the Mediterranean, and from the Atlantic about 42° lat. and 40° long., in a north-easterly course, quite outside, but at no great distance from, the British Isles, and thence towards the North Cape. Of the tracks more immediately influencing British weather, are one from Iceland in a south easterly direction through the North Sea and Germany, and three tracks starting from near Sicily, one eastward through the north of Germany, the second to the north-east to Christiania, and the third through Ireland and the Hebrides, these being the storm-tracks which chiefly give the British Islands their easterly and northerly winds. Gen. Hazen's charts suggest valuable hints as to the times of the year when these and other important routes are most frequently taken by storms.

THE U.S. FISH COMMISSION AT WOOD'S HOLL.[1]

THE summer head-quarters of the United States Fish Commission is located at Wood's Holl, a village situated on the south side of Cape Cod, Mass., north of Martha's Vineyard. The coast scenery is pretty, and inland the country is undulating and partially clothed with forests of pines and other trees, which have mostly been planted within the last forty years. Wood's Holl and the neighbourhood is an increasingly favourite locality for the summer residences of the inhabitants of Boston, New Haven, New York, and other large towns in that part of the country, and already a colony of scientific men is making its appearance. Excursion steamers run frequently in the summer for the day trip from Newport and other places. As in the whole of that region of North America, the surface-soil is a thick deposit of glacial drift containing numerous boulders.

The site was selected on account of the purity of the water, owing to the absence of all fresh-water streams and presence of strong tidal currents which ensure a circulation of well-aërated water close to the shore, and also on account of the physical conditions which lead to a remarkable variety in the marine fauna being procurable within a short distance.

The warm current of the Gulf Stream, which sweeps up the eastern coast of the States, here becomes diverted by Cape Cod, and passes out into the Atlantic. This causes the pelagic fauna to be well represented, and were the local conditions of the coast more favourable it would cause the littoral fauna to be particularly rich. The cold currents from the north extend down the coast as far south as Cape Cod, which practically forms the southern limit of the Arctic littoral fauna. The narrow neck of the Cape thus separating two entirely distinct assemblages of animal forms. Lastly, the deep sea offers its peculiar fauna.

The site occupied by the Commission consists of a small spit of land, which was purchased by public subscription, and which has since been increased by reclamation.

At the present time the buildings of the Fish Commission are in a transition state. Formerly, the various

[1] ...ually spelt and still pronounced "Wood's Hole." The name was ... by order of the Postmaster General in 1873.

officers had to severally obtain what accommodation they could in the village. Last August, however, the staff moved into the residence-house which has been built for that purpose. The residence-house is a red brick, gabled structure, with plenty of outside woodwork, a style of architecture which is very common in New England. On the ground-floor is a large central hall, into which open Prof. Baird's office, the sitting-room, dining-hall, reading-room, and other offices. A portion of the first floor is reserved for Prof. Baird and his family, the remainder is devoted to the bedrooms of the married officers who have brought their wives—families to the extent of one baby only are allowed! The bachelors' rooms are on the second floor. The whole building is most comfortably furnished. All the staff take their meals together with the ladies.

Hitherto the summer work of the naturalists has been carried on in two roughly-fitted barns. One serves mainly as a storehouse for the trawls, collecting implements, and jars and bottles for preserving specimens. Here also is the laboratory where the chemical investigations on the water obtained at various depths and from different localities are carried on.

The other building, which is on the wharf of the Light-house Board, is mainly devoted to the temporary storage of the zoological collections and to the work-tables of the naturalists, all the fixtures are of a very simple character, and call for no special mention. It is here that the material brought in by the steamers is finally sorted and, as far as possible, determined and catalogued; the material collected, however, affords more than enough occupation for the winter months.

A commodious new laboratory is being built close to the residence house, which is expected to meet all the requirements of this most important section of the Commission. It will be a plain three-storied brick building, in the basement of which will be large tanks. The ground-floor will be thrown open to the public as a general aquarium, in which will be tanks of various sizes for the illustration of the marine fauna and for the breeding of fish, much as in our ordinary aquaria. The first floor will be devoted to the laboratories of the working naturalists, to which of course the general public will not be admitted. The second floor will be divided between the physical and physiological laboratories, photographic room, and other work rooms.

Between this building and the residence-house is the pumping-station, by means of which fresh and salt water can be continuously circulated throughout either building.

On the sea-frontage several large open basins or tanks are nearly completed, in which fish-hatching will be carried on on an extensive scale. Cod-hatching is to be tried next season. The tanks are large enough to breed sharks, were they required. The water in these tanks rises and falls with the tide, owing to the porosity of the outer walls and the existence of small gratings; the latter are, however, under perfect control. Prof. Verrill has suggested that it would be desirable to have a kind of iron and glass cage or diving-box made, which, while open above, could be let down into the largest tank, and in which a person could observe and sketch the marine life around him under the most favourable conditions.

A long wharf has also been constructed for the use of the steamers of the Commission, and which also serves as a breakwater.

The general scheme of the buildings leaves little to be desired, and doubtless many improvements and additions will suggest themselves from time to time.

Not far from the Commission buildings is a plot of ground, which has been secured for the purpose of building a teaching and research laboratory, to be supported by those universities and colleges which do not possess any similar facilities of their own. This appears to be a very wise provision, and doubtless the Commissioner

will afford every possible facility to those who may work them.

Not less complete are the arrangements for the collection of specimens and for the observations on depth, surface and bottom temperatures, and other physical features.

Two steamers have been built for the Fish Commission—the *Fish Hawk* in 1880, and the *Albatross* in 1883.

The *Fish Hawk*, a steamer of 484 tons of displacement and 205·71 tons measurement, was built particularly for use in the hatching of shad-eggs. Although unsuitable for long voyages or rough weather, she has proved a valuable boat for short trips and for dredging down to a depth of about 700 fathoms, having been well furnished with modern apparatus. Already much important work has been accomplished in the vessel in her subsidiary capacity, as is proved by the publications of the Fish Commission and Prof. Verrill's articles in *Science*, &c. (*Science*, vol. i. 1883, pp. 443, 531, and vol. ii. 1883, p. 153).

Last year the new steamer *Albatross* was specially constructed for deep-sea trawling. The extreme length of the vessel is 234 feet, the breadth of beam, moulded, is 27½ feet; the registered net tonnage is 400 tons, and the displacement, on a 12-foot draught, 1000 tons. She is most perfectly fitted with all those improvements in collecting and observing tackle which considerable experience has proved to be the best; but improvements and adaptations are continually being suggested. A full and illustrated account of the vessel is given by Mr. R. Rathbun in *Science*, vol. ii. 1883, pp. 6, 66. Suffice it now to mention that the comfort of the staff is as well provided for as their scientific necessities, and a complete system of electric lighting enables the laboratory work to be carried on at all hours. The main laboratory is 20 feet long, 26 feet wide, and 7 feet 10 inches high, and is situated amidships: above this is a well-lighted deck laboratory.

So far we have very briefly detailed the mere appliances for the collection and preservation of specimens. A short sketch of the mode of work might prove interesting.

The steamers are manned by naval officers and crew, a plan which serves the double purposes of lessening the expenses of the Commission and of spreading an interest in marine zoology throughout the navy. The officers have proved themselves to be most zealous in the work, and have cordially assisted the civilian staff in every possible manner; several important improvements in dredging and sounding apparatus have originated from some of them.

The sailors, too, take a personal interest in their occupation, and occasionally bring rare forms to the naturalists, which they have themselves caught in a hand-net.

Before an expedition, Prof. Baird consults with Prof. Verrill on desirable localities to explore, and instructions are given to the Commander, who also has charge of the mechanical portion of the dredging operations.

Mr. Benedict is the naturalist in charge of the vessel, and he is responsible for the specimens directly they arrive on deck; usually one or two naturalists work under his directions, the arrangement being that each is responsible for one or more groups of animals.

The contents of the trawl are subjected, immediately on their arrival on deck, to a process of sifting through a series of sieves of different sized meshes, and most of the animals are forthwith preserved. Numerous methods of conservation have been tried, but it is found that, under the special circumstances, alcohol is the best for general purposes. In some instances the jars have to be kept in ice to preserve the tissues whilst the alcohol is slowly penetrating; picric, chromic, osmic, and other acids and reagents, are used when deemed necessary. As a general rule, pelagic forms are killed by picric acid. All but the largest and smallest animals are put into glass-capped "butter-" and "fruit-jars," which are secured by a screw-down metal cap. Various devices are resorted to for large specimens; the smallest are placed in homœopathic vials.

Each dredging "station" has its serial number, and a full record of the position, depth, bottom and surface temperatures, with other details, is kept, and a label, bearing the number of its station, with certain other information, is put into each bottle of specimens. Mr. Benedict has a small hand-press on board, and he often prints such labels whilst the trawl is out. So far as opportunity presents, the species or groups are roughly sorted on board, and are then ready for identification in the laboratory. Excepting in the case of large quantities of common species, all the specimens from each haul are retained. Surface skimmings are similarly treated.

All the material so obtained passes through Prof. Verrill's hands, and he distributes certain groups to specialists to be worked out after he has described those forms which interest him. The zoological work of the Commission is so well known that it would be superfluous to even enumerate the naturalists on the staff.

After having been duly entered, the specimens, if properly named, are broken up into sets, of which the first naturally goes to the National Museum at Washington, the second to Prof. Verrill, the third to the Museum of Practical Zoology at Harvard University, Cambridge, Mass., and the remaining sets are variously distributed or kept in the stores as duplicates.

The Marine Laboratory is only officially open during the summer months. During the remainder of the year most of the officers are at Washington employing their time in identifying specimens, drawing up reports, and other routine work.

The biological portion of the work of the Commission is not merely restricted to the collection and identification of species; careful drawings are being made of every form collected, with a view to illustrating the entire fauna of that coast. The numerous papers of Prof. Verrill, Dr. Ryder, and others, prove that anatomical and embryological investigations are not neglected; life-histories are studied, and all possible data are collected on the influence of environment on organisms. It is intended, when the new building is completed, that the physiology of marine forms shall receive a due share of attention.

One object of the Commissioner is to thoroughly study the fauna of the American waters, fresh and salt, and encouragement and facilities are given to all the officers to follow their personal bent, of course paying a due regard to routine work. Naturally, at present, the officers are more engaged in the recording of species, since this pioneering work is the necessary precursor to morphological investigation; but the lines of the Commission are laid on too broad a scale to limit the original research of any officer.

ALFRED C. HADDON

ANCIENT AIR-BREATHERS

WHILE the records of the life of the sea have been preserved in abundance from early geological periods down to the present time, the chronicles of the living things of the land are comparatively scanty. The early history of land-animals has therefore a peculiar interest, heightened by the rarity of the evidence from which the history must be compiled. Considerable progress, however, has recently been made in this department of investigation. Within a few years, discoveries of the remains of scorpions and insects have successively been made in older and older strata, till now they have been disentombed almost simultaneously from older Palæozoic rocks in three different countries of the old world. Scorpions, which appear to be the most ancient type of air-breathing arachnids, have been found to be comparatively abundant in the lowest Carboniferous strata. The

first Palæozoic scorpion which came to light was described by Count Sternberg, in 1835, from a specimen obtained by him from the coal-formation of Chomle, near Radnitz, in Bohemia, which, in 1836, was named *Cyclophthalmus senior* by Corda.[1] Three years later Corda gave an account of another scorpion, from the same locality, under the name of *Microlabis*. From that time till 1866 these were the only Palæozoic scorpions known, but in the latter year Messrs. Meek and Worthen described two new genera from the Coal-measures of Mazon Creek, Morris Grundy County, Illinois, under the names of *Eoscorpius* and *Mazonia* respectively.[2] In 1873 Dr. Henry Woodward showed that scorpion remains, referable to the genus *Eoscorpius*, occur both in the Coal-measures of England and in the Carboniferous Limestone series of Scotland.[3] In 1881 the present writer had the privilege of studying and describing a large suite of scorpion remains belonging to the Geological Survey of Scotland, and obtained by their officers from the lowest Carboniferous rocks of the Scottish Border. The results were published in the *Transactions* of the Royal Society of Edinburgh, where several species belonging to the genus *Eoscorpius* were described and figured.[4] In that paper the following conclusion was announced:—"Although there seems to be sufficient reason to separate the genus (*Eoscorpius*) from any recent one, these ancient scorpions appear not to differ in any essential character from those now living. As far as the horny test, the only part now preserved to us, is concerned, they were as highly organised and specialised towards the beginning of the Carboniferous period as their descendants at the present day. It is unfortunate on that account that Messrs. Meek and Worthen should have chosen the name *Eoscorpius*, for the dawn of the scorpion family must have been at a much earlier period, and we may hope that their remains will yet turn up in the Devonian and Silurian plant-beds when these come to be thoroughly searched." The subsequent study of a much

FIG. 1.—Fossil scorpion found in the Silurian rocks of the island of Gothland (Sweden). From the photograph sent by Prof. Lindström to M. Alph. Milne-Edwards (from *La Nature*).

finer collection from the same rocks has fully confirmed the conclusion as to the essential identity of structure between the living and the Palæozoic forms. The hope also expressed in the passage just cited has now been realised by the discovery of scorpions in the Upper Silurian beds of Scotland and Sweden, in the former by Dr. Hunter of Carluke, who obtained one from Lesmahagow in Lanarkshire in June 1883, and in the latter by Prof. Gustav Lindström, of the Swedish Academy of Sciences, Stockholm, who got his last summer (1884) from Wisby in the Swedish Island of Gothland. Prof. Lindström shows that his was a land animal and a true air-breather, and though of a more lowly type than the Carboniferous and recent scorpions, was yet to be placed among the members of that ancient family. Writing to M. Alphonse Milne-Edwards on November 24, 1884, he says:—

"The specimen is in sufficiently good preservation, and shows the chitinous brown or yellowish brown cuticle, very thin, compressed and corrugated by the pressure of the superposed layers. We can distinguish the cephalothorax, the abdomen, with seven dorsal laminæ, and the tail, consisting of six segments or rings, the last narrowing and sharpening into the venomous dart. The sculpture of the surface, consisting of tubercles and longitudinal keels, entirely corresponds with that of recent scorpions. One of the stigmata on the right is visible, and clearly demonstrates that it must have belonged to

[1] Corda, in *Böhmischen Verhandlungen*, 1836, and Wiegmann's *Archiv*, 1836, vol. ii. p. 380. Figured in the *Transactions* of the Bohemian Museum.

[4] *Transactions* of the Royal Society of Edinburgh, vol. xxx. pp. 397-412, Plates XXII., XXIII.

an air-breathing animal, and the whole organisation indicates that it lived an dry land. In this scorpion, then, which we have named the *Palæophoneus nuncius*, we see the most ancient of land-animals. In the conformation of this scorpion there is one feature of great importance, namely, four pairs of thoracic feet, large and pointed, resembling the feet of the embryos of several other tracheates and animals like the Campodea. This form of feet no longer exists in the fossil scorpions of the Carboniferous formation, the appendices belonging to which resemble those found in the scorpions of our own day."

To Prof. Lindström is thus due the honour of first announcing the discovery, and it was not till Dr. Hunter had received a photograph of the Swedish specimen, together with a preliminary notice of his find from Prof. Lindström, that he became fully aware of the importance of his own discovery. On receipt of the photograph and the notice, Dr. Hunter showed the Scottish specimen to the present writer (December 1884), with whom he has agreed to describe the geological and zoological aspects of the find.[1] In the meantime, a short preliminary description for comparison with the Swedish animal may not be out of place here. The rocks from which the Scottish example was obtained are the well-known Upper Silurian beds of Dunside, Logan Water, Lesmahagow, Lanarkshire, which have yielded such a magnificent suite of Eurypterids, and supplied a great part of the materials for Dr. Henry Woodward's work on the Merosomata. The animal in this specimen is about an inch and a half long, and lies on its back on the stone. Its exposed ventral surface shows almost every external organ that can be seen in that position, and in this way serves to supplement the evidence supplied by the Swedish specimen. As in the northern individual, the first and second pair of appendages of the cephalo-thorax in the Scottish example are chelate, but the palpi are not quite so robust. The walking-limbs, though not so dumpy as in *P. nuncius*, also terminate each in a single claw-like spike. The arrangement of the sternum shows a large pentagonal plate (metasternite), against which the wedge-shaped coxæ of the fourth pair of walking-limbs abut. The coxæ of the third pair bound the pentagonal plate along its upper margins, and meet in the mid-line of the body, where they are firmly united. The coxæ of the first two pairs, as well as the bases of the palpi, are drawn aside from the centre line of the body, showing that, as in recent scorpions, these alone were concerned in manducation, or rather the squeezing out of the juices of the prey. From the circumstance of these being drawn aside, the medial eyes are seen pressed up through the cuticle of the gullet, and a fleshy labrum (camerostome) appears between the bases of the cheliceræ.

Behind the pentagonal plate and the coxæ of the hindmost limbs there succeeds a space shaped like an inverted V, where the test is thin and wrinkled in the line of the long axis of the body. It is just along this line that the trunk or abdomen most easily separates from the cephalo-thorax in recent scorpions, and it is at once apparent that the trunk in this case is as far separated from the cephalo-thorax as it can well be without being detached. Similar longitudinally-wrinkled skin is seen to unite the dorsal and ventral scutes up the whole right side of the trunk. At the interior angle of the inverted V there hangs downwards a narrow bifid operculum flanked on each side by the combs, which have each a broad triangular rachis set along its lower edge with the usual tooth-like filaments. The combs almost hide the first of the four ventral sclerites, which bear the breathing apparatus in recent scorpions, notwithstanding which all four of these exhibit on their right side undoubted slit-like stigmata at the usual places. The fifth ventral scute of the trunk suddenly contracts posteriorly, and to its narrow end is articulated a long tail of five joints and a poison-gland with a sting. These joints are all constructed on the same principle as those of recent scorpions, and as the articular surfaces are more highly facetted on the dorsal than on the ventral aspect (a portion of the tail of the specimen lying sideways allowing of these observations), there can be no doubt that the animal was in the habit of carrying the tail over the head (so to speak) and stinging in the same manner as its recent congeners.

The above characters are shown in the accompanying woodcut (Fig. 2) on nearly the same scale as that of the figure of the Swedish example, viz. about twice the natural size, taken from a drawing made by the writer. From it and the description it becomes apparent that the animal was a true air-breather and a land-animal.

The presence of the remains of these ancient murderers

FIG. 2.—Fossil scorpion from the Upper Silurian rocks of Lesmahagow, Lanarkshire, Scotland, found by Dr. Hunter, Carluke; magnified two diameters.

in such old strata necessarily suggests the question, What was the nature of their victims? As far as the Carboniferous scorpions are concerned, we are acquainted with several other arachnids, numerous hexapod insects, and chilognathous myriapods, which might have formed their prey. The Middle Devonian rocks of Canada have furnished remains of dragon-flies, which were known as the oldest land animals until the present writer showed, in 1882, that chilognathous myriapods were far from uncommon in the Lower Old Red Sandstone of Forfarshire in Scotland,[1] and the *Gyrichnites* of the Lower Devonian of Gaspé are doubtless the casts of such animals.[2] It is but a short step from the Lower Old Red Sandstone of Scotland to the Upper Silurian. The lowest part of the Lower Old Red Sandstone, which is a lake-formation, may be represented elsewhere by marine strata, which would undoubtedly be called Upper Silurian, and, in fact, high up in the Lower Old Red Sandstone of Lanarkshire, which contains *Cephalaspis*, a band of shale occurs,

[1] It has been erroneously stated in the *Annals and Magazine of Natural History*, p. 76, and elsewhere, that the specimen was sent to me in 1883. The above statement is the correct one.—BEN N. PEACH.

[1] *Transactions* of the Royal Physical Society, 1882, vol. vii. pp. 177-188, Pl. II.

[2] *Transactions* of the Royal Society of Canada, vol. i. Pls. xi., xii.

which proves that marine conditions recurred for a short time, and brought again into the lake basin such marine Silurian forms as *Beyrichia*, *Orthoceras*, and even *Graptolites*.[1] We are not left to conjecture the nature of Silurian insect-life, for Mr. Charles Brongniart intimated to the Paris Academy of Sciences (December 29, 1884), through M. Alphonse Milne-Edwards, the discovery of a fossil insect, the rock containing which is the Silurian sandstone of Calvados, and which is even more ancient than the strata containing the Swedish and Scottish scorpions. The specimen consists of the wing, the characteristics of which are those of the wings of Blattæ.

It may be that, as recent scorpions feed extensively on the eggs of various Invertebrates, the Silurian species also visited the shores for the eggs of animals left bare by the tides, among which *Parka decipiens*, the eggs of its marine allies, the Eurypterids (if the latter had the habits of their near relation, the recent king-crab), would form a *bonne bouche*. If this suggestion should prove to be well founded, we may suppose that it was this habit of frequenting the shores that led the present specimens to be imbedded in marine strata, as from their completeness they could not have been borne far from their native shores.

BEN. N. PEACH

NOTES

We greatly regret to record the death of Dr. J. Gwyn Jeffreys, F.R.S., from a sudden attack of apoplexy, on Saturday last, at the age of seventy-six years. We hope to refer at length, in our next number, to Dr. Jeffreys's scientific work.

Sir William Thomson will on Monday give an address at the opening of the fine laboratories at University College, Bangor. In the evening there will be a *conversazione*.

The premium of the Society of Telegraph Engineers and of Electricians was presented, at the annual meeting, to Prof. George Forbes, F.R.S.E., for his paper on "The relation which should subsist between the strength of an electric current and the diameter of conductors to prevent over-heating." The Fahie premium was presented to Mr. W. H. Stone, M.A., for his paper on "The physiological bearing of electricity on health." The Paris Electrical Exhibition premium was presented to Mr. H. C. Mance for his paper on "A method of eliminating the effects of polarisation and earth-currents from earth-tests." Having presented the premiums and thanked the members for their support during his year of office, Prof. Adams vacated the chair and introduced the president for 1885, Mr. C. E. Spagnoletti.

At the recent meeting of the Government Grant Committee, Prof. Ewing, of Dundee, received a grant of 100*l.* to institute observations of earth movements on Ben Nevis. He was asked to undertake this work by the Directors of the Observatory there, and he intends to look both for minute earth tremors, such as have been observed by Rossi and Bertelli in Italy, and for slow movements of the horizon, such as those observed by Messrs. G. H. and H. Darwin at Cambridge. The isolated position of the Ben Nevis Observatory makes it particularly well suited for observations of this kind.

Sir Joseph Lister, Professor of Clinical Surgery in King's College, London, has been appointed by the German Emperor a Knight of the Order Pour le Mérite for Science and Arts.

We have received from the Fine Art Society a "remark" proof of a very fine etching, by Mr. Flameng, of Mr. Collier's portrait of Prof. Huxley, which attracted so much attention at the Royal Academy Exhibition two years ago. Doubtless many of our readers will remember the leading features of the portrait, the etching of which will form a suitable companion to that of Mr. Darwin by the same engraver, also from a painting by Mr. Collier.

The first arrangement for supplying private houses with electricity is now in working order in Paris. It has been placed in the Passage des Panoramas, Galerie Vivienne, for the use of all the houses in this extensive block. The motor being a gas-engine, the use of which is legal in cities, the proprietors of this lighting establishment have nothing to do with civic authorities and regulations. Six or seven shops are now lighted by about 100 Woodhouse and Rawson incandescent lamps.

The Russian Government are preparing an expedition to Western Siberia, for the purpose of examining some sulphur deposits recently discovered there. The natives have for many years had knowledge of these deposits, but the Government have only recently been made cognisant thereof, through a report by Lieut. Kallayn. According to the statement of M. Konschin, a mining engineer, one of the deposits contains upwards of five million pood of sulphur, the number of the former being ten. Europe has hitherto been supplied with this article from Sicily, and it is hoped that the Russian deposits may compete with the mines in that island. In Russia sulphur has hitherto only been found at Tchirkota, not far from Petrofisk, in Daghestan, which has chiefly been delivered to the powder-mills. The expedition in question will leave St. Petersburg next month.

Mr. H. Cecil writes to us with reference to our note on the British Museum lectures last week. "To some of us," Mr. Cecil writes, "it is a source of no little astonishment that the materials of these lectures, some of them of such surpassing interest, should not be made accessible to students and the general public in some full, substantial, and permanent form. Besides, it would surely pay. The hunger of men never was keener for every single seed-corn of threshed-out verity; and I am myself constantly asked with reference to the subjects of these very lectures: Where can I find this in accurate form, vouched by the writer's name, and open to the examination and judgment of all men?"

A Michigan paper gives an account of a phenomenon that was witnessed in Orion and vicinity on the evening of December 20:—At Marshall a bright luminous ball of large dimensions, tinged with a deep green, apparently lit up the whole heavens. The light was instantly followed by a loud noise, somewhat resembling distant thunder, which continued for about one minute. The general opinion is that it was an aerolite. At Jackson the vibration was preceded by a vivid flash in the heavens, resembling lightning. The phenomena were noticed in several portions of the city. To the south it was felt quite strong. Near Hanover and Horton the quaking of the earth was observed, while the heavens for an instant were lighted by an instantaneous flash, followed by a loud report. Buildings were slightly jarred, and the people noted the motion of their houses.

The Rev. H. Sumangala, High Priest of Adam's Peak, Ceylon, has recently contributed to the *Orientalist*, a magazine published at Kandy, a short summary of the views of Hindu astronomers on the form and attraction of the earth. The theory of Bhâskara, who flourished in the twelfth century of our era, was that the terrestrial globe, which is composed of earth, air, water, space, and fire, is of a spherical shape, and being surrounded by planets, such as the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn, and by the orbits of stars, stands firm in the midst of space by its own power, without any other aid. This, he says, is a well-ascertained fact. Like the pollen in the Kadamba flower, on its surface are countries, mountains, gardens, and buildings, where Râkshasas, men, Devas, and Asuras dwell. He refutes the theory that the earth cannot stand of itself without any support by arguing that, if there be

[1] A. Geikie, "Explanation of Sheet 23 of Geological Survey of Scotland," 1878, p. 14.

a material support to the earth, there must be another upholder of that, and again another of this, and so on; then there will be no limit, and if, ultimately, self-support must be assumed, why not assume it in the first instance? Is not the earth one of the forms of Siva? As by nature heat is in the sun and fire, coldness in the moon, fluidity in water, hardness in stone, so mobility is in the air, and immobility in the earth. Each object has its own faculty, and "wonderful indeed are the faculties implanted in objects." As to the attraction of the earth, Bhāskara observes that the earth, possessing an attractive force, draws towards itself any heavy substance situated in the surrounding atmosphere, and that substance appears as if it falls. But whither, he asks, can the earth fall in ethereal space, which is equal and alike on every side? He ridicules the Buddhists for holding that the earth descends in unbounded space. An astronomical work anterior to Bhāskara's time says the terrestrial globe possesses Brahma's most excellent power of steadiness, and remains in space. The succession of day and night is said to be caused by the rising and setting of stars, the planet, and the zodiac. Arya Bhatta, in the sixth century, maintained the existence of a diurnal rotation of the earth round its own axis. The sphere of the stars, he states, is stationary, and the earth itself, making a revolution, produces the daily rising and setting of stars and planets.

MR. HOFFMANN, of Washington, has addressed a letter to the Anthropological Society of Paris, stating that in various ancient burial places in Southern California, and in the islands of Santa Cruz, Santa Rosa, and San Miguel, he has found instruments which he believes to be those employed in tattooing. The natives here do not tattoo themselves now, with the exception of the Haida Indians of Queen Charlotte's Island; they only paint their faces, but still many individuals bear traces of tattooing. Mr. Hoffmann found vessels containing red ochre and cakes of a black substance, composed apparently of the hydro-oxide of manganese, as well as some very sharp needles of bone, wood, and the fins of fish. These needles are still preferred, by tribes which practise tattooing, to those of steel, which they could procure easily.

THE publications of the Russian Geological Commission succeed one another rapidly, each of them containing some important contribution to the geology of Russia. The third fasciculus of its *Memoirs*, just published, contains a monograph by M. Tschernyschen, on the Devonian deposits of Russia. The interest awakened by the recent explorations in the Ural Mountains, where deposits quite analogous to those of the Hartz and the Eifel have been discovered, induced the author to describe some of the old collections of the Palæontological Museum at the Mining Institute at St. Petersburg, namely, that of Meglitzky and Antonoff, from the shores of Lake Kotluban, in the Southern Ural. These fossils proved to be Upper Devonian, and many of them quite new for the Ural region; they also enabled the author to give the following scheme of the Devonian deposits of the Ural mountains:—The Lower Devonian is represented by schists and sandstones, with numerous remains of *Atrypa hatilingius*, Schmer, and by the limestones of Nyaze-Petrovsk and Yurezan (upper part of the Lower Devonian), which are akin to the Greifenstein limestones and the Wissenbacher schists of Germany. The Middle Devonian consists of sandy limestones and unfossiliferous marls, which appear on the Ay and Yurezan rivers from beneath dolomites. The rich fauna of the former corresponds to that of the Eifel. And, finally, the Upper Devonian is represented by the limestones of Lake Kotluban, of Murzataeva, River Vilva, the mouth of Sulema, &c.; it corresponds to the Cuboides and Goniatites schists of the Eifel and Hartz, and is covered by the Clymenia limestones of Verkhneuralsk, which appear, in the Hartz, above the so-called *Intumenscens-stufe*. Comparing further the Devonian deposits of the Ural with those of the Petchora, as described by Keyserling, of the Government of Orel, according to his own observations, and of North-Western Russia, the author arrives at the following interesting conclusions:—On the Petchora we have Lower Devonian deposits of the Vol and Ukhta rivers, akin to the Middle Devonian of the Ural and Western Europe; and an upper layer (on the Middle and Lower Ukhta) which corresponds to the Goniatite schists of the Ural and the *Goniatites intumescens* deposits of the Rhine. The Middle Devonian of the Ural and Petchora correspond to the dolomitic limestones of Livonia and to the lower deposits of the south-east, which are rich in corals and tentaculites. For several interesting details we must refer, however, to the paper itself, which is followed by a *résumé* in German (twenty-four quarto pages), and is accompanied by three plates representing Devonian fossils.

THE geological map of Russia, prepared by the Geological Commission, is well advanced, and during this year we expect the appearance of three sheets including a part of the Ural Mountains, the government of Kostroma, and the Volga-and-Don region. As to the last issue of the *Izvestia* of the Commission, we notice in it a paper by M. Mikhalsky on the structure of the Kielce Mountains and the surrounding region. Its chief features were already known from the explorations of Pusch and Rœmer, but the very age of the deposits of this region (Devonian, Trias, Jura, and Chalk) had to be determined with more precision. The Trias reaches a great development, and M. Mikhalsky confirms Prof. Rœmer's affirmation that all three chief subdivisions of the German Trias are found in Poland. The Jurassic formation is also represented by three different deposits: one of them closely corresponds to the Jurassic deposits of Southern Germany, namely, to those of Bavaria, as already indicated by Ludwig Ammon. Another, which contains the *Exogyra virgula*, together with *Gryphæa dilatata* and *Pecten inæquicostatus*, seems to be an intermediate deposit between the Oxfordian and Kimmeridge deposits of England. As to the Oolite, its fossils are more like those of France and Middle Germany, but substantially differ from those of South Germany. A series of Jurassic deposits at the Peklo village is interesting, as it affords a remarkable mixture of the Upper Jurassic fauna of Middle Europe with the Jurassic fauna of Russia. It contains the ammonite *Perisphinctes virgatus*, which has been found only in the Russian Jurassic formation. As to the Chalk, it is represented in the south-west by much dislocated deposits containing *Inoceramus Crispii* and *I. striatus*, both characteristic of the Senonian subdivision. The whole is covered with thick deposits of Boulder Clay, containing Scandinavian and local boulders; one boulder of granite has been observed on the summit of the northern chain of the Kielce ridges, and, judging from the general character of the glacial deposits, the author believes in the extension of the Scandinavian ice-sheet as far as the Kielce ridge.

Science states that the U.S. Bureau of Navigation of the Navy Department reports that 145 compasses with the four-needle card have been issued to ships during the past year, and that they have given general satisfaction, the behaviour of the improved compasses used by the Greeley relief expedition in high latitudes being especially commended. This expedition gathered considerable data concerning the variation of the compass in high latitudes, but, owing to its speedy return, none were obtained concerning the magnetic force and dip. The data concerning compass variations, collected by the Department during the past year, are in course of preparation for publication. Professional paper No. 17, entitled the "Magnetism of Iron and Steel Ships," is in the press; and No. 18, on "Deviations of the Compass in U S. Naval Vessels," is nearly ready. Preparations have been made for a careful examination of the magnetic character of the new steel vessels, and a compass station is to be

established in Narragansett Bay. The instruments for a compass testing-house are now in the possession of the Bureau, and a building will be erected when the appropriation is made. In view of the probable necessity of compensating the compasses of these new vessels, a binnacle has been designed in the Bureau for this purpose, and it will be placed in the *Dolphin* to be tested.

In accordance with a recommendation of the recent Geodetic Conference, we learn from *Science* a series of observations for latitude is to be made at the U.S. Naval Observatory, which, taken in connection with a similar series made elsewhere, and compared with observations made after an interval of some years, will assist in determining whether there are any slow changes taking place in latitudes upon the earth. Lisbon, which is very near the same parallel as Washington, is expected to co-operate with the Naval Observatory. The observations will be made with the prime vertical instrument; and at Washington a line officer of the navy will be detailed for the work, which will probably require several years.

At University College, London, Dr. J. A. Fleming will commence a course of lectures and demonstrations on Modern Applications of Electricity in the Arts, on Friday, February 6, at 4 p.m. The first lecture will be open to the public without payment or tickets.

The *Revue Scientifique* now publishes a weekly supplement containing reports of the proceedings of the Paris scientific societies; this supplement may be obtained separately.

The additions to the Zoological Society's Gardens during the past week include a Mouse (*Alces machlis*) from Russia, presented by Mr. Evelyn Hubbard; a Goshawk (*Astur palumbarius*), British, presented by Mr. W. H. St. Quintin, F.Z.S.; a Pink-footed Goose (*Anser brachyrhynchus*), British, presented by Major W. H. Fielden, C.M.Z.S.; two Yaks (*Poephagus grunniens*) from Tibet, six Dunlins (*Tringa alpina*), British, purchased.

GEOGRAPHICAL NOTES

At the meeting of the Paris Geographical Society on the 9th inst. M. Maunoir read a paper on the explorations of Capt. Aymonier in Indo-China in 1883 and 1884, during which he collected many epigraphical documents and notes on Northern Laos and the basin of the Mouna. On December 10 the traveller was to leave Saigon for Binh-Thuan, in the extreme south of Annam, to study the monuments left behind by the Cham. It is wholly new ground. A letter was read from the French Consul at Zanzibar giving the latest geographical news from Eastern Africa. M. Delondre summarised his recent exploration in Malacca. M. Paul Fauque, who is charged by the Ministry of Education with a scientific mission to Sumatra, described the results of his journey, and gave more details on the character, manners, and customs of the natives of the Siak country and of the Kingdom of Acheen. He added much valuable information on the geography, natural history, and mineralogy of this great island. His collections are to be distributed amongst various museums in France. The following medals were awarded:—A gold medal to M. de Foucauld for his journey in South Morocco and his exploration of the southern extremity of the Atlas Mountains; a gold medal to Dr. Neis for four journeys in Indo-China and in the hitherto unexplored parts of Laos; the La Roquette prize to the Danish summary of geological and geographical enterprises in Greenland (*Meddelelser om Grønland*); the Jernard prize to M. Leroux, the publisher, for the volume of documents on the history of geography from the thirteenth to the sixteenth century; and the Echard prize to M. Dumas Vorzet for maps and cartographical labours. M. Allain referred to the defectiveness of geographical education in some public educational establishments, and advised that all the State libraries in Paris should be provided with as complete a collection as possible of geographical works.

The editor of *Petermann's Mittheilungen* has issued a circular with the January number of his journal, giving notice that in future the monthly parts will consist of three main sections: (1) Original papers, as heretofore; (2) a monthly report of the advances of geographical discovery and colonisation in countries outside Europe; (3) a literary section referring to recent geographical and cartographical works, with the exception of pure travels, which will be dealt with in the second section. The valuable supplementary parts (*Ergänzungshefte*) will be continued as before.

The report has been published of a journey by four French officers among the Muongs of the Black River, which enters the Red River of Tonquin a little below Sontay. These tribes are described as more civilised than the Mois of Cochin China; they are practically independent, although the Annamites profess to appoint their chiefs; they are very warlike, intelligent, and industrious, making their own arms, which are sometimes very beautiful. After having acquired all the information they could as to Muong silk and silk manufactures, the travellers explored the mountainous regions among the district. There are gold mines in the hills worked by Chinese, but at some of them they have armed themselves in great numbers since the recent troubles, and will allow no one, French or Muong, to approach them. The members of the expedition, however, saw enough to convince them that the district is rich in minerals, especially gold.

The Argentine expedition to the Chaco will, it is stated, have the result of adding a large territory to civilisation and agriculture. This forms for the most part the basin of the Rio Bermejo, or Red River, which flows down from the Andes, and commences to be of importance towards the 61st degree of longitude. Soon after it receives the waters of the Tenco, and should be navigable unless its bed is obstructed by the trunks of trees and if it does not traverse lagoons where its channel will be difficult to find. It flows in a south-westerly direction, and enters the Rio Paraguay after a course of about 500 kilometres. The districts through which it flows are well-wooded; they are inhabited by tribes of Indians, whose favourite weapon is the arrow, and who, when they do not live by hunting and fishing, exist on the locusts which abound and on the cattle which they can contrive to steal from the Argentines. The number of inhabitants of this part of the Chaco is estimated at 10,000.

Globus publishes a letter from Dr. Claus, a member of the Steinen expedition into one of the most unexplored parts of Brazil. It was for some time doubtful whether the expedition was examining the Xingu, or some other neighbouring tributary of the Amazon. It appears now that the Xingu was the river explored. On May 26, 1884, the expedition left Cuyabá, the capital of the Brazilian province, Matto Grosso, arrived on July 20 at Rio Batovy, and in the end of October at Pará, at the mouth of the Amazon. Dr. Claus writes that they completely carried out their programme. After a journey of two months from Cuyaba, they sailed in canoes down a small river, which, according to the maps, should belong to the Xingu region. The districts around the source of this river are inhabited by numerous tribes who have never met with whites, and who use only implements of stone and bone. At the 12th parallel they came on the Xingu. The cataracts caused the travellers the utmost difficulty, and they also suffered much from hunger. For a whole month they had nothing but beans to eat. During part of the descent of the Xingu, also, they met with the same troubles and privations; but towards the end of their journey they fared much better, passing along from one Indian village to another. On October 15 they arrived at the first Brazilian settlement on the 4th parallel. The head of the expedition has a large collection of Indian objects, and the collections of the others, though much damaged by water, are otherwise safe.

Mr. Wm. Cameron, F.G.S., an indefatigable explorer of Malayan countries, has just prepared, at Singapore, a large and elaborate map, on a scale of half an inch to the mile, of districts recently explored by him in Selangor, Ulu Selangor, Sungei Ujung, and other parts of the Malay Peninsula. The map is said to be excellently drawn up, and to be a valuable acquisition to our existing geographical knowledge of the Malay Peninsula, which is somewhat limited.

A geographical conference is about to be held in Melbourne on the occasion of the first annual meeting of the Victorian branch of the Geographical Society of Australia. Members of the general council of the Society, as well as of the local councils

of the New South Wales and Victorian branches, are invited. Among the subjects to be discussed are the necessity of defining the exact meaning of the geographical term Australasia, the compilation of a reliable work on the geography of Australia for Australian schools, the exploration of New Guinea, and the discovering and defining of the exact boundaries of what may now be termed British New Guinea.

ASTRONOMICAL PHENOMENA FOR THE WEEK

1885, FEBRUARY 1-7

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on February 1

Sun rises, 7h. 40m.; souths, 12h. 13m. 53·2s.; sets, 16h. 47m.; decl. on meridian, 16° 58′ S.: Sidereal Time at Sunset, 1h. 35m.

Moon (2 days past Full) rises, 18h. 22m.*; souths, 1h. 23m.; sets, 8h. 12m.; decl. on meridian, 8° 21′ N.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. on Meridian ° ′
Mercury	6 31	10 33	14 35	22 3 S.

Saturn, February 1.—Outer major axis of outer ring = 44″·5; outer minor axis of outer ring = 20″·1; southern surface visible.

February 1, 7h.—Jupiter in conjunction with and 4° 9′ north of the Moon.

SCIENCE IN VICTORIA

THE President of the Royal Society of Victoria devoted a considerable portion of the presidential address contained in the last published volume of the Society's *Transactions* to a review of the progress of science in the colony. It might at first sight be supposed that, in young communities like those of the Western States of America or of our own Australasian colonies, the struggle to develop their resources to the utmost, which occupies every one, and the total absence of a leisured class, would be an insurmountable obstacle to scientific work, or indeed to work of any kind for its own sake. But the numerous and valuable publications which we constantly receive from scientific societies formed among young English-speaking communities all over the globe—in Japan, China, the Straits, Ceylon, Australia, Canada, the United States, the Cape, and many other places—show that this impression is wholly incorrect, and that the members carry with them into scientific work the energy and perseverance which they exercise in their ordinary avocations.

The first sign of progress which Mr. Ellery had to chronicle in his address was that the Royal Society had grown too large for its building, and consequently the more spacious rooms of the Melbourne Athenæum had to be selected for the annual address. The number of members has increased annually, and the financial condition of the Society is satisfactory. During the year under review there has been "a vigorous and healthy progress," but the young body, having outgrown its juvenile garments, must provide itself with more capacious ones in the shape of considerable additions to the Royal Society house. In the several national scientific and technical departments the year has been one of active labour, and their progress, in common with that of the Society, has been considerable. There is, the President reports, an undoubted and general increase in the desire for knowledge in the various pure and applied sciences, and especially as applied to technical training and to the daily requirements of life. New societies for the prosecution of study and research, more especially in the natural sciences, have come into existence in the provinces, and the older societies and schools are increasing in their influence and usefulness. The School of Technology and the technological museums at Melbourne are growing rapidly. An example of the great economic benefits of such institutions was afforded during the year under review by the opening of a new trade between Victoria and India wholly on account of the knowledge derived in Melbourne from the museum collection of Indian woods, and it is anticipated that a like result will accrue from a collection of colonial economic woods sent to Calcutta. In Ballarat and Sandhurst the schools of mines are important centres of teaching in the arts and in applied and natural sciences. In Melbourne itself the Medical and Pharmaceutical Societies, the Microscopical Society, and especially the Field Naturalists' Club, have partaken in the general progress.

The President then comes to the question of what has actually been done in Victoria during the year towards the advance of natural science. The first person referred to in this connection is Baron Mueller, to whose research is due a large proportion of what is known of Australian botany. He succeeded in getting the Colonial Government to purchase for the Botanical Museum the collection of Dr. Sanders of Hamburg, a leading authority on algæ, and on European and North African botany. Valuable additions, illustrative of the flora of the western coast districts of Australia, were made to the same museum, which has really been formed by Baron Mueller himself from his collections, extending over nearly forty-four years. Among new publications of the year were additions to the "Fragmenta Phytographia Australis," a continuation of the "Systematic Atlas of the Eucalypti," a new edition of a work on "Select Plants for Industrial Culture," and "A Systematic Census of Australian Plants." A second volume of the vegetable fossils of the auriferous drifts was completed, and in its pages are described and compared most of the fossil fruits of the Pliocene period. A vast field of investigation still remains in the fossil foliage of the Miocene deposits. With a reference to the work of the Melbourne Observatory during the year the president closes that portion of the address with which we are specially concerned here. At the end of the address he argues that the Royal Society is broad enough in its constitution to embrace all sciences, and that, therefore, various sections in connection with it should be formed rather than new societies for each science. The community is not, he thinks, yet large enough to maintain, in an effective state, a number of scientific societies; and if all in Victoria interested in the progress of science, or engaged in her various byways, were to unite together, not only would more useful work be done, but the work would be more valuable, on account of being subjected to a wider criticism. All the colonial scientific societies combined would form a strong body, capable of fostering and even subsidising scientific research. In one respect, perhaps, the wheels of the Society might run more smoothly. The volume (a rather small one) of the *Transactions* for 1883 was not issued till May 30, 1884, and was not delivered in London until more than six months later.

THE KILIMANJARO EXPEDITION

AT a meeting of the Royal Geographical Society held on Monday night, Mr. H. H. Johnston gave a description of his visit to Kilimanjaro, on the slopes of which he spent more than five months in the summer and autumn of last year.

Mr. Johnston began by explaining the circumstances in which, as appointed leader of the expedition projected by the joint Kili-

mmittee of the British Association and the Royal ciety, he found himself on arriving at Zanzibar without any trained collectors to assist him. Giving a lively and picturesque narrative of his adventures during his stay with Mandara, chief of Moshi, a person of remarkable character, who rules a small tract on the lower slopes of Kilimanjaro at an altitude of about 6000 feet, and is at war with all the surrounding potentates, Mr. Johnston told how, after some difficulties, he began the ascent of the mountain with forty carriers and some guides provided by another chief, Marango. They crossed the cultivated zone, which ended at about 5500 feet in that part, entered a healthy district with pleasant grassy knolls and many streams of running water, and encamped beside a lovely fern-choked brook at 6500 feet, the whole ascent being very gradual. The following day they passed through stunted forest, not unlike an English woodland, where the trees, however, were hung with unfamiliar ferns and creepers, and where deliciously scented parasitic begonias trailed their pink flower-bells from branch to branch. The dracæna, which is cultivated by the Wa-Chagga to form hedges, here grew wild. Tree-ferns were abundant and handsome. Above 7000 feet the orchilla moss draped the forest trees in long gray festoons. Tracks of elephants were very numerous. The other noticeable inhabitants of the forest were dark blue touracous and tree-hyraxes. Wart-hogs were occasionally met with up to 8000 feet. At 9000 feet they encamped for the night by a small spring of water in the midst of a grand bit of forest, not of that stunted character which marked the lower woods. He caught a chameleon and many beetles here, and also shot touracous and pigeons. The next day they walked several miles eastward to find a good place for settlement close to water, and not too high up, so that his shivering followers might not suffer unreasonably from cold. He selected an admirable spot on a grassy knoll rising above the river of Kilema, which takes its source near the base of Kimawenzi. The altitude of this spot was nearly 10,000 feet. Having seen every one carefully installed and protected from the—to them—severe cold (for the thermometer descended every night to one or two degrees below freezing-point), he transferred his own quarters to a higher elevation, and began industriously to collect. His first excursion was to the base of Kimawenzi. The terrible hurricans of wind, however, that raged round this jagged series of lava peaks, prevented him from continuing the ascent, although he doubted if it were possible for any one to reach the summit, owing to the want of foothold. The snow varied very much in quantity on Kimawenzi. Sometimes the whole peak would be covered down to the parent ridge, with only the precipitous rocks peeping blackly through the mantle of white. At other periods the snow would be reduced to an insignificant patch, and the reddish sand which filled the crevices and glissades between the lava rocks would be left exposed to view. This change from an almost complete snow-cap to nearly no snow at all might be effected in twelve hours. His great object, however, was to reach the snows, and, if possible, the summit of Kibô. To do this it would be necessary to sleep on the way. He had therefore to induce a few followers to accompany him to carry impedimenta. Starting at 9, he walked upwards with few stoppages until 1.30. At first they crossed grassy undulating hillocks, the road being fairly easy. Then they entered a heathy tract, scorched and burnt with recent bush-fires; but higher up, where the blaze had not reached, the vegetation was fairly abundant and green. Small pink gladioli studded the ground in numbers. At an altitude of nearly 13,000 feet bees and wasps were still to be seen, and bright little sun-birds darted from bush to bush, gleaning their repast of honey. A little higher they found warm springs, the thermometer showing the temperature of the trickling mud to be 91° F. Mounting high above the rivulet the scenery became much harsher. Vegetation only grew in dwarfed patches as they passed the altitude of 13,000 feet, and the ground was covered with boulders, more or less big, apparently lying in utter confusion, and without any definite direction. They were not very difficult to climb over, and even seemed to act as irregular stone steps upwards. In their interstices beths of the size of large shrubs grew with a certain luxuriance. About 13,700 feet he saw the last resident bird, a kind of stonechat apparently. It went in little cheery flocks, and showed such absence of fear that he had to walk away from it before shooting to avoid shattering his specimen. After this, with the exception of an occasional great high-soaring kite or great-billed raven, he saw no other bird. On reaching a height a little above 14,000 feet he stopped again to boil the thermometer and refresh himself with a little lunch. Throughout this ascent, which was easy to climb, he suffered absolutely nothing from want of breath or mountain sickness, although his three Zanzibari followers lagged behind, panting and exhausted, and complained much of their lungs and heads. "Mounting up a few hundred feet higher than the last stopping-place," Mr. Johnston said, "and rounding an unexpected and deep ravine, I arrived close to the base of a small peak which had been a conspicuous and useful point to aim at during the whole journey from my station. I was now on the great mountain-ridge of Kilimanjaro, and could see a little on both sides, though the misty state of the atmosphere prevented my getting any good view of the country. This ridge, which from below looks so simple and straight, is in reality dotted with several small mountains and cut up into many minor ridges, the general direction of which is, on the southern side, from north-east to south-west. To the eastward I could see the greater part of Kimawenzi rising grandly with its jagged peaks and smooth glissades of golden sand. Westward, I still looked vainly in the piled up clouds, for the monarch of the chain still remained obstinately hidden, and I was at a loss as how to best approach his awful crown of snow. At length, and it was so sudden and so fleeting that I had no time to fully take in the majesty of the snowy dome of Kibô, the clouds parted, and I looked on a blaze of snow so blinding white under the brief flicker of sunlight that I could see little detail. Since sunrise that morning I had caught no glimpse of Kibô, and now it was suddenly presented to me with unusual and startling nearness. But before I could get out my sketch-book and sharpen my chalk pencil, the clouds had once more hidden everything, indeed, had inclosed me in a kind of London fog, very depressing in character, for the decrease in light was rather alarming to one who felt himself alone and cut off at a point nearly as high as the summit of Mont Blanc. However, knowing now the direction of my goal, I rose from the clammy stones, and, clutching up my sketch-book with benumbed hands, began once more to ascend westwards. Seeing but a few yards in front of me, choked with mist, I made but slow progress; nevertheless, I continually mounted along a gently-sloping hummocky ridge, where the spaces in between the masses of rock were filled with fine yellowish sand. There were also fragments of stone strewn about, and some of these I put into my knapsack. The slabs of rock were so slippery with the drizzling mist that I very often nearly lost my footing, and I thought with a shudder what a sprained ankle would mean here. However, though reflection told me it would be better to return to my followers and recommence the climb to-morrow, I still struggled on with stupid persistency, and at length, after a rather steeper ascent than usual up the now smoother and sharper ridge, I suddenly encountered snow lying at my very feet, and nearly plunged headlong into a great rift filled with snow that here seemed to cut across the ridge and interrupt it. The dense mist cleared a little in a partial manner, and I then saw to my left the black rock sloping gently to an awful gulf of snow so vast and deep that its limits were concealed by fog. Above me a line of snow was just discernable, and altogether the prospect was such a gloomy one, with its all-surrounding curtain of sombre cloud and its uninhabited wastes of snow and rock, that my heart sank within me at my loneliness. Nevertheless, I thought, 'only a little further, and perhaps I may ascend above the clouds and stand gazing down into the crater of Kilimanjaro from its snowy rim.' So, turning momentarily northwards, I rounded the rift of snow, and once more dragged myself, now breathless and panting, and with aching limbs, along the slippery ridge of bare rock which went ever mounting upwards. I continued this for nearly an hour, and then dropped exhausted on the ground, overcome with what I suppose was an ordinary attack of mountain sickness. I was miserably cold, the driving mist having wetted me to the skin. Yet the temperature recorded here was above freezing-point, being 35° F. I boiled my thermometer, and the agreeable warmth of the spirit-lamp put life into my benumbed hands. The mercury rose to 183°·8. This observation when properly computed, and with the correction added for the temperature of the intermediate air, gives a height of 16,315 feet as the highest point I attained on Kilimanjaro. I thus came within a little more than 2000 feet of the summit, which is usually estimated to reach an altitude of 18,800 feet." He made other ascents during the month he was in high altitudes. The footprints and other traces of buffaloes were seen up to 14,000 feet, but he never caught sight of one of the creatures, nor did he see any of the big antelope,

who also wander up to the snow line. At a height of 13,000 feet he saw three elephants, and at night the shrill trumpeting of these animals could be heard round the station. On October 18 he found himself, most unwillingly, obliged to leave the elevated settlement and return to Taveita. The relatively great cold they had experienced had reacted very unfavourably on his men's health, and he feared that a longer delay might render them quite unfitted to carry burdens. He intended, however, to make his return journey entirely through a new and hitherto untraversed country, and this project somewhat consoled him for leaving the summit of Kilimanjaro still unconquered. Their downward journey, part of the way through trackless bush and dense dank forest, was not without adventure and some reward in scenery of great beauty. The average elevation of this country was between 8000 and 7000 feet, and the temperature consequently almost cool, ranging from 43° at night to 70° in the mid-day warmth. After some four hours' walking from their camp they crossed the long ridge that marked the southern flank of Kimawenzi, and began to descend the eastern slope of the mountain. Soon they emerged on a kind of heath-like country, and then looked forth on a splendid view stretching from Mwika to the mountains of Bura and Ukambani (the Kiulu range), with Jipe on one hand and the River Tzavo on the other. After some enjoyable excursions from his settlement at Taveita, finding that his funds would not support the expedition beyond the end of November, he made a rapid journey to the coast by way of Pare, Usambara, and the Rufu river to Pangani. At Zanzibar, finding there were no fresh funds to enable him to return to Kilimanjaro, he paid off the last of his faithful followers, many of whom had accompanied Thomson on his great journey, and took his passage on the British India steamer to Suez in quite a sulky frame of mind, as sorry to leave his beautiful mountain as many people are to quit England. Travelling overland from Suez, he arrived in London not much more than six weeks after he had caught his last glimpse of the snows of Kilimanjaro.

A SCANDINAVIAN LAND OF OPHIR

WE learn from *Naturen* that the little island in the Hardanger Fjord, known as Bömmelöen, which two years ago was an uninhabited and desolate spot, is now a busy scene of extensive gold-digging. Numerous English artizans and Norsk bricklayers and carpenters have for months been actively engaged in boring and sinking shafts into the rock, and in preparing houses and shelter for the men and machinery that have been drawn hither by the report of the discovery in 1882 of gold in the Storhangen mine. This discovery had been anticipated in 1862 by the find of a piece of pure gold, which was at once deposited in the mineralogical museum of Christiania, where it has since remained apparently unheeded, although the place and time at which it was found are duly marked on the corresponding label. After twenty years gold was again found in 1882, at the Storhangen mine, which was then being worked for copper ore. The result of this discovery was the purchase, in 1883, of the works by an English firm, trading under the title of the Oscar Gold Mining Company, which is worked under the scientific direction of Mr. Murchison. Considerable amusement seems so have been created among Norsemen by a somewhat ambiguous statement, set forth in the Company's circulars, which oracularly announces that "the gold finds at Bömmelöen are either Nature's greatest success or her greatest illusion"!

The geological formation of Bömmelöen is similar to that of other auriferous rocks, the gold being found in quartz, which occurs in strata never more than six feet thick, although of considerable extent, and generally underlying green (chloritic) schist. The greenstones of the island differ from those found in other parts of Norway, and contain glass and various typical vulcanic products.

The operations of the Oscar Mining Company have given a new stimulus to the search for gold in Norway, and we learn that Herr Bakke, Inspector of Mines at Trondhjem, has officially reported the discovery of virgin gold in a piece of chloritic slate from Stegen in Nordland, while it is authoritatively stated that gold has been found within the last year or two at Sveen in the Bergen-Amt, and also near Stavanger. In the latter case the discoverer, Nils Berg, an old experienced Australian gold-digger, washed the gold from the mud remaining at the bottom of a shaft that had been sunk in a copper mine.

SCIENTIFIC SERIALS

Wiedemann's Annalen, vol. xxiv. January 1885—O. Lehmann, on the melting-points of bodies in contact, and on the electrolysis of solid iodide of silver. A remarkable paper, accompanied with an elaborate plate describing phenomena of crystallisation observed chiefly with microscope at limiting edge of two crystallisable liquids or solutions. Iodide of silver presents certain closely-related phenomena under electrolysis, both in molten and in solid condition. Regular crystalline iodide of silver conducts an electric current, the silver being carried in the direction of the negative current through the crystal without its structure being disturbed. In its electrolysis, however, there appears a streaking in the direction of the flow of the current.—W. von Bezold, on a new kind of cohesion-figures. These experimental researches relate to the quasi-dendritic forms observed when one liquid descends through another.—L. Boltzmann, on the possibility of founding a kinetic theory of gases on attractive forces alone. This is an attempt to dispense with Maxwell's hypothesis that molecules repel one another in the inverse fifth power of the distance, which he framed to account for the apparent perfect elasticity exhibited by molecules of gases. Boltzmann proposes a new theory, based on attraction, very similar to that recently independently propounded by Sir W. Thomson (NATURE, August 28, 1884).—O. Chwolson, on the calibration of the plug-rheostats of Siemens and Halske. This discusses corrections for the resistance of connecting-pieces, &c.—F. Kohlrausch, the electric conductivity of water distilled *in vacuo*. A column of pure water 1 metre long and of 1 square millimetre section has a resistance of about 4×10^{10} ohms.—G. Kirchhoff, on the change of form which an elastic body experiences when it is magnetically or dielectrically polarised. This paper, originally published in the *Proceedings* of the Berlin Academy, deals analytically with the phenomenon of electrostriction investigated by Lorberg and others.—A. Schuster, on the discharge of electricity through gases. Treats of certain points in dispute between the author and Profs. Goldstein and E. Wiedemann. The author pronounces in favour of the view that all the phenomena of effect of magnetism, &c., upon the discharge of the negative electrode may be explained if it be admitted that the negatively-charged portions of the gaseous molecules are driven off from the kathode.—E. Goldstein, on electric conduction in the vacuum. Discusses some experiments in which a carbon filament lamp was employed; the filament forming one electrode, a platinum wire being inserted through the glass to serve as another electrode for the discharge, which was obtained, without an induction-coil, with electromotive forces of about 300–350 volts.—Werner Siemens, contributions to the theory of magnetism. Describes experiments on partially-closed magnetic circuits of iron, giving rise to the opinion, that the harder a specimen of iron is, the greater is the value of the magnetising force at which the maximum of permeability is observed. Also, the magnetic resistance of air is from 480 to 500 times as great as that of iron.—H. Hertz, on the dimensions of unit of magnetic pole strength in different systems of measurement.—E. Ketteler, the optical constants of magnetic media. Develops equations relating to Kundt's recent magneto-optic observations.—E. von Fleischl, the double refraction of light in fluids. Proves that in optically-active liquids the rotation is due to the existence of double refraction. Double-refracting liquids have no optic axis, and the wave-surface consists of two concentric spherical sheets.—W. von Voigt, on the measurement of the refractive indices of absorbing media. Recommends the prism method as more accurate than the total-reflection method.—W. von Voigt, on the theory of reflection and refraction at the boundary of crystalline media. New equations based on the author's theory of the reactions between matter and ether in transparent media, and leading to same conclusions as Kirchhoff's older theory.

Journal de Physique, November, 1884.—J. Jamin, on hygrometry. The author proposes to substitute for the "relative humidity" a new coefficient termed the "hygrometric richness," which is the ratio of the actual pressure of aqueous vapour of the air to the difference between the total atmospheric pressure and the actual vapour pressure. The substitution appears to be both rational and instructive.—Ch. Rivière, essay on cooling power of gases. Confirms formula of Dulong and Petit up to 400° C., but above that temperature the observed values are lower than the theoretical. Also appears to prove that at very low pressures cooling power is independent of the chemical composition

of the gas.—C. Decharme, imitation of the phenomena of electricity and magnetism by means of liquid and gaseous currents. Summarises number of experimental researches.—A. Kundt, electromagnetic rotation of plane of polarisation of light transmitted through films of iron, cobalt, and nickel; an abstract from the Berlin *Berichte*.—E. Bazzi, on the heat developed by a current during the variable period. Experiments show Joule's law still to hold good, assuming Helmholtz's equations true. It has been remarked by Blaserna that this is not incompatible with the existence of oscillations in the extra-current, for Helmholtz's expression, though only a first approximation which omits the terms that would express these oscillations, is probably not far from the mean result.—The remainder of this number consists of abstracts of papers by Amagat, Bailie, H. Pecquerel (on infused rays), Cornu, Witz, and by Berthelot and Ogier from the *Annales de Chimie et de Physique*.

December, 1884.—E. Villari, new researches on the electric figures of condensers. The ramifications observed in the dust-figures are believed to be due to partial internal discharges.—E. Villari, microscopic researches on the traces of electric sparks engraved on glass, and on the diameter of these sparks. Tinted zones are observable where these sparks have passed over the surface of the glass. These traces vary with the glass, not with the nature of the electrodes; they are not removed by acids, and are probably due to heat. The cross section of the spark is, for a constant potential, proportional to the charge which produces it.—E. Villari, on the total heat developed by one or more sparks generated by the discharge of a condenser.—E. Villari, singular mechanical effect of the electric discharge. Glass plates, even strong thick ones, are easily broken by the spark of a Leyden battery, provided one face be silvered.—A. Righi, on a recent interpretation of Hall's phenomenon. Bidwell's theory of Hall's phenomenon appears to fail in the case of bismuth, in which Hall's phenomenon exists most markedly. It is also to be remarked that the variation of the electric resistance of bismuth, when subjected to the magnetic field, is greater than that of any other metal.—K. Weber, the electric siren. This instrument produces tones in a receiving telephone by causing rheostomes having different numbers of peripheral contacts rotated at a uniform speed to interrupt the circuit of a battery. The author draws a number of conclusions relatively to the partial and resultant tones, which are hardly justified when one considers the non-sinusoidal character of the variations of the current.—F. Melde, acoustical experiments, abstracted from *Wied. Ann.*—P. de Heen, determination of the general law governing the dilatation of any chemically definite liquid. The author assumes that the molecules attract one another in the inverse seventh power of the distance. Whatever may be thought of the hypothesis, there is an interesting coincidence running through his figures.—The remainder of the number is filled with abstracts of papers from the *Nuovo Cimento*, the most important of them being by E. Wiedemann, on the density of the luminiferous ether, and by Profs. Bellati and Romanese, on some remarkable thermic properties of the iodides of silver and copper.

Rendiconti del Reale Istituto Lombardo, December 11, 1884.—Report on the results of the International Medical Congress held at Copenhagen during the month of August, by Prof. G. Sangalli.—On the influence of high temperatures on the development of microbes, by Prof. L. Maggi.—A study of the earthquake which occurred at Ischia on July 28, 1883, by Prof. Giuseppe Mercalli.—On the secular variation in the elements of terrestrial magnetism at Como, by C. Chistoni.—Descriptive catalogue of sixty-three hitherto unpublished Pontifical coins and medals in the Royal Numismatic Cabinet at Milan, by E. B. Biondelli.—The paintings of the Italian masters in the public museums of Europe, in connection with Senator Morelli's recent work, by Prof. G. Mongeri.—Critical notes on the fourth book of the pseudo-Theophilus, by Prof. C. Ferrini.—Meteorological observations made at the Brera Observatory, Milan, during the months of November and December 1884.

Journal of the Russian Chemical and Physical Society, vol. xvi. fasc. 7.—On the heat of combustion of organic matters, by W. Longuinine; being a description of the methods resorted to by the author in his series of determinations preliminary to the subsequent publication of the results obtained. The paper is accompanied by several plates.—Analysis of a saltpetre earth from Turkestan, by N. Lubavin. It is taken from the ruins of Kunya-Urgench, the climatic conditions being altogether very favourable for its formation, and its abundance explains the cheapness of gunpowder at Khiva. It contains 6 per cent. of azotic anhydride. The remarks of the author as to the connection between the formation of saltpetre and the inundations of the Amu are worthy of notice.—Review of the Russian chemical literature for the year 1883 and first quarter of 1884.—We notice the appearance of a fifth edition of the excellent manual of analytic chemistry by M. Menshutkin, as also of his lectures on organic chemistry (lithographed), which are now in print; a third edition of P. Alexeyeff's organic chemistry, and a second edition of the principles of chemistry, by A. Potylitsin, not to speak of several translations. As to separate monographs, besides those already mentioned by NATURE, the following are worthy of notice:—The organic compounds of thein relations to the haloid salts of aluminium, by G. Gustavson—a work which has obtained the premium of the Chemical Society; on the relations between the compositions and refractory power of organic compounds, published at Kazan, which has raised a serious and useful discussion between Russian chemists; and an inquiry into the atoms and the measurement of their size, by O. Tmyanovski (Warsaw).—On the electrical discharge in gases, by M. Goldhammer; being a series of experiments for determining the temperature in Geissler tubes. When rarefied air is taken for the experiment, its heating does not depend on its elasticity so long as this last remains within the limits of 8·4 to 38 millimetres; but it decreases with the decrease of the electrical current. The distribution of temperature on the surface of the tube is shown by a series of curves. An interesting observation made by the author is that phosphorescent light on the surface of the glass, such as Prof. Crookes considered as appearing only at pressures equal to millionth parts of an atmosphere, appeared also at pressures from 1·3 to 0·8 millimetres, the glass of the tube not belonging to the category of uranic glass, and the phosphorescent light appearing invariably on the calode, even when the direction of the current has been changed.—Preliminary report on the influence of compression of iron and steel on their magnetisstion, by P. Bakhmetieff.—On the hail of July 11, 1884, at Kharkoff, by N. Pilschikoff—a description, with figures, of the hailstones.—On the shock of absolutely rigid bodies, by N. Joukovsky; being a mathematical critique of the theories advanced on this subject by MM. Matson, Prof. Shilley, at Kieff, and M. Garrigou-Lagrange.—On the dilatation of liquids, by M. SOCIETIES AND ACADEMIES

LONDON

Royal Society, January 8.—"Experimental Researches in Magnetism." By Prof. J. A. Ewing, B.Sc., F.R.S.E., University College, Dundee. Communicated by Sir William Thomson, F.R.S.

The paper describes in detail experiments of which preliminary notices have already been published in the *Proceedings* of the Royal Society, vol. xxxiv. p. 39, and in the *Philosophical Magazine*, November, 1883. The experiments relate to:—

(1) The magnetic susceptibility of iron and steel, the form of the magnetisation curve, and the changes of magnetism caused by cyclic changes of magnetising force.

(2) The influence of vibration on magnetic susceptibility and retentiveness.

(3) The influence of permanent strain on magnetic susceptibility and retentiveness.

(4) The energy expended in producing cyclic changes of magnetisation.

(5) The ratio of residual to total induced magnetism.

(6) The changes of induced and residual magnetism caused by changes of stress.

(7) The effects of constant stress on magnetic susceptibility and retentiveness.

(8) The changes of magnetism caused by changes of temperature.

(9) The effect of temperature on magnetic susceptibility.

The experiments were conducted on pieces of metal which gave as near an approach to the condition of uniform magnetisation as is practically attainable.

Curves are given which show the behaviour of iron and steel in various states of temper when subjected to a first application

of magnetising force, and also to subsequent cyclic changes of magnetising force, such as complete or partial removal and re-application, or reversal. The curves are drawn by plotting either $\mathfrak{I}$, the intensity of magnetisation, or $\mathfrak{B}$, the magnetic induction, in relation to $\mathfrak{H}$, the magnetising force: the characteristics of these curves and their relation to the physical state of the piece under examination are pointed out. Curves so drawn invariably exhibit the static lagging action to which the author (in a former paper) gave the name "hysteresis," any cyclic change of $\mathfrak{H}$ giving rise to a more or less nearly closed *loop* in the curve. Attention was previously drawn to these loops by Warburg, who also anticipated the author in pointing out their important physical meaning, namely, that the area of a loop, or $-\int \mathfrak{I} d\mathfrak{H}$, is the measure of the energy expended in performing the cycle of magnetisation which the loop describes. In the present paper numerous absolute measurements of this energy are given, especially of the energy which is thus dissipated in each reversal of the magnetism of a piece of iron or steel. These show that while the dissipation of energy by reversal of magnetism is very much smaller in soft iron than in hard iron or steel, even in the latter its amount is very trifling, so that the principal part of the heat which is produced in the cores of electro-magnets must be due chiefly to other causes than this static hysteresis, and is, in fact, due almost wholly to the induction of so-called Foucault currents in the cores. The relation of this hysteresis to Weber's theory of molecular magnets, as extended by Maxwell, is discussed, and the insufficiency of Maxwell's extension noticed.

By vibrating a piece of soft iron during the application and removal of magnetising force, the effects of hysteresis are almost entirely removed, and the iron is then found to possess almost no retentiveness. But when the application and removal of magnetising force are effected without mechanical disturbance, the retentiveness of soft iron is found to be even greater than that of steel. In some cases 93 per cent. of the whole induced magnetism of a piece of annealed iron was found to remain on the complete removal of the magnetising force. It is pointed out that there is no discrepancy between this result and the well-known fact that a *short* iron core of an electro-magnet retains almost no magnetism when the current in the magnet is interrupted. In that case the ends of the magnet itself, after the interruption of the current, exert a sufficient reversed magnetising force to destroy almost entirely the residual magnetism. But when tested under the conditions which give uniform magnetisation and avoid the demagnetising influence of the ends, soft annealed iron is more retentive than even the hardest steel.

Examples are given showing that the influence of permanent set in the curve of magnetisation is so marked as to give a criterion by which a strained piece may be readily distinguished from an annealed piece of metal, and that strain diminishes very greatly the magnetic retentiveness of iron.

Numerical values of the coefficients of permeability (μ) and of susceptibility (κ) are given for a number of samples of iron and steel, and the relation of these coefficients to $\mathfrak{B}$ and $\mathfrak{I}$ is exhibited graphically after the manner of Rowland. The greatest value of μ refers to soft annealed iron while under mechanical vibration, and is about 20,000.

The next part of the paper deals at great length with the effects of stress (consisting of longitudinal pull) on the magnetic susceptibility and retentiveness of iron; and the last part deals more briefly with the effect of temperature on magnetism, a subject already largely treated by G. Wiedemann and others.

The experiments, which have been of a very extended character, were made during 1881-83 in the laboratory of the University of Tokio, Japan, with the help of Japanese students, Messrs. Fujisawa, Tanakadate, Tanaka, and Sakai, to whom the author is indebted for much valuable assistance. The results have been, almost without exception, reduced to absolute measure, and are for the most part presented graphically in curves which accompany the paper.

January 22.—"On the Origin of the Proteids of the Chyle and the Transference of Food Materials from the Intestine into the Lacteals." By E. A. Schäfer, F.R.S.

The most important result obtained by the author is the establishment of the fact that, during absorption of food from the intestine, the lymph corpuscles migrate in large numbers into the lacteals, and for the most part become disintegrated and dissolved in the chyle. This is the case not only after a meal containing fat, but also after feeding with substances devoid of that alimentary principle; it is, therefore, a phenomenon of general occurrence during absorption, and the carrying of fatty particles into the lacteals after a meal containing fat by the immigrating leucocytes, must be regarded as merely incidental to a more general function.

The immigration and solution of numerous leucocytes in the contents of the lacteals must be the means of conveying a large amount of proteid material, derived from their dissolved protoplasm and nuclei, into the chyle. And any other material which may be mechanically or otherwise incorporated with their protoplasm must also be set free. In this way the fatty particles which they contain during absorption of a meal containing fat become released and suspended in the chyle, and it is probable that amyloid matters are also in part thus conveyed to that fluid.

A fuller account of the whole subject, furnished with illustrations and containing the necessary references to other articles dealing with the same question, will appear in the forthcoming number of the *Monthly International Journal of Anatomy and Histology*.

Geological Society, January 14.—Prof. T. G. Bonney, F.R.S., President, in the chair.—Ewan Cameron Galton, Henry Brougham Guppy, Henry G. Hanks, and William Elliott Howe were elected Fellows of the Society.—The following communications were read:—The metamorphism of dolerite into hornblende schist, by J. J. Harris Teall, F.G.S.—Sketch of the geology of New Zealand, by Capt. F. W. Hutton, F.G.S., Professor of Biology in the Canterbury College, University of New Zealand. The paper commenced with some general remarks on the importance and variety of the geology of New Zealand, and on the progress made in the investigation of the islands. The author then proceeded to the question of the classification of the sedimentary strata, which the author arranges in the following local systems:—

Systems	Probable age
Recent	Recent
Pleistocene	Pleistocene
Wanganúi	Newer and Older Pliocene
Pareóra	Miocene
Damarú	Oligocene
Waípara	Upper Cretaceous
Hokanúi	Lower Jurassic and Triassic
Maítaí	Carboniferous
Tákaka	Silurian and Ordovician
Manapoúri	Archæan

Most of these systems are divided into several local series. The general geological structure was then treated. The south island of New Zealand was shown to be traversed from near the southern extremity to Tasman's Bay by a curved anticlinal, convex to the westward; and the strata to the east of this axis are thrown into secondary folds, which mainly affect the beds older than Tertiary. A great north and south fault occurs west of the anticlinal. The north island is very different. It is traversed by a narrow ridge, the country northward of which is broken by three great volcanic cones, Mount Egmont, Ruapehu, and Tongariro near the centre of the island. The oldest rocks seen south of Cook's Straits are not repeated to the north, and a fault may traverse the Straits. The rock systems up to the Hokanúi, inclusive, are similar in lithological character throughout New Zealand, and appear to have been formed on the shore of a continent with large rivers. The higher systems, with the exception of a few coral-reef limestones, are locally variable, and may be considered insular. The relative distribution of sedimentary and eruptive rocks was briefly noticed, and the occurrence of some useful minerals mentioned. No workable coal is found below the base of the Waípara system. A description of the different systems and of the series into which they are divided followed, commencing with the oldest. The distribution, lithology, and thickness of each system were noticed briefly, and lists of the most important fossils were added. The eruptive rocks associated with each system were next noticed in the same order, and the paper concluded with notes on the distribution of volcanic rocks in the north island, on hot springs, and on the minerals found in New Zealand.—The drift deposits of Colwyn Bay, by T. Mellard Reade, F.G.S.

Zoological Society, January 20.—Prof. W. H. Flower, F.R.S., President, in the chair.—Mr. Sclater called attention to the breeding of a pair of the Chinese Blue Magpie in the Society's Gardens in 1884, and exhibited specimens of their eggs.—Prof. Bell exhibited some models illustrating the paper of Rathke on the development of the great blood-vessels in the

ed in 1884. The President, Mr. R. H. Scott, is address, in which he stated his intention to ral state of the science of meteorology over the e l with the programme sketched out by Prof. n the *Report* of the British Association, 1840. ere now six meteorolo ical societies publishing n addition, six periodicals almost exclusively cience. He went on to say:—"With all this ture there is one particular in which, in this our science labours under a great disadvantage. r aware, no instruction is given in it except at d College, Greenwich. In Germany, in the r, no less than eleven courses of lectures are s many Universities or high schools." Mr. e large map showing all the observing stations and also the distribution of information as to gy as contained in the Meteorological Office. He the different classes of observations proposed by different classes of stations and the degree to stions had been carried out.—The next subject ts which have been made by balloon ascents, as, &c., to gain a knowledge of the condition of sphere; and Mr. Scott stated that, on inquiry s foreign institutions which possessed affiliated ns, he had found that, except in the case of gton, none of the observations were practically forecasting. No telegrams are received from n one particular all authorities are agreed, that suggested any mode in which the barometrical be used, owing mainly to the uncertainty about to sea-level from great heights.—Mr. Scott con- es with a notice of the important work by Padre the Havannah, on the West Indian hurricanes 7.—The following gentlemen were elected the uncil for the ensuing year:—President: Robert , K.S.; Vice-Presidents: William Morris Beau- , John Knox Laughton, F.R.A.S., Edward I.S., Charles Theodore Williams, M.D.; Trea- Perigal, F.R.A.S.; Trustees: Hon. Francis ussell, M.A., Stephen William Silver, F.R.G.S.; eorge James Symons, F.R.S., John William Foreign Secretary: George Matthews Whipple, ncil: Edmund Douglas Archibald, M.A., George Inst.C.E., John Sanford Dyason, F.R.G.S., atson, M.A., William Ellis, F.R.A.S., Charles ard Inwards, F.R.A.S., Baldwin Latham, obert John Lecky, F.R.A.S., William Marcet, ert Edgar Peek, F.R.G.S., Capt. Henry A.S.

SYDNEY

ociety of New South Wales, November 26. Wilkinson, F.L.S., F.G.S., President, in the lowing papers were read:—On a new and re- ce of symbiosis, by William A. Haswell, M.A., *austrodii*, found by the author in Port Jackson, ribed to a preliminary note in the *Proceedings* of l. vii. p. 606), forms colonies, the individuals of chambers or tubes in a common soft matrix elled filaments. The whole colony grows round ome in such a way as to form a complete tube *ensis* doubtless profiting by the action of the the tentacles of the anemone, in killing or inute organisms that come in contact with them ogonidiæ of the Australian coast, with descrip- ecies, by William A. Haswell, M.A., B.Sc. In h is a review of all the Australian species, seven e described: *Nymphon validum* and *wynnegeus armatus*, n new genus and species; *Ascho* and *assimilis*; *Colossendeis tenuissima* and *tuberosum*.—Notes on the Port Jackson Crustacea, ton, B.A. Some new species are here described, s are made on the sexual and other peculiarities ertain genera.—Descriptions of Australian micro- E. Meyrick, B.A.; No. xii. Œcophoridæ (con- paper continues the *Œcophoridæ* as far as the fifty additional species are described, of which w to science.—A monograph of the Australian ii., by R. von Lendenfeld, Ph.D. The author description of the known Australian species of ges, fifty-two in number. To the species described by Carter, Haeckel, Poléjaeff, and Ridley, numerous new ones are added. A new classificatory system is established in this paper. The Calcisponginæ as an order are divided into Poléjaeff's two sub-orders, the meaning of which has, however, been slightly changed. To Haeckel's three families and Carter's Teichonidæ three new families are added.—Notes on the direction of the hair on the back of some kangaroos, by N. de Miklouho-Maclay. The peculiarity of inverted hair on the back of some of the kangaroo tribe is traced by the Baron in the genera *Dorcopsis*, *Dendrolagus*, and in one species of *Osphranter* (*Osphranter rufus*). The paper also contains some remarks on the dentition of *Dendrolagus Dorianus*.—Note on *Tribrachyrinus Clarkei*, M'Coy, by F. Ratte, M.E. The previous descriptions of this fossil were taken from imperfect inner casts only. Mr. Ratte has now been enabled to describe thoroughly and illustrate this beautiful crinoid from an outer cast of the calyx in the Australian Museum. The most important additions to previous descriptions are the ornaments of the surface of the calyx, the attachment of the first brachial article, and the plates of the roof of the calyx.—On the larvæ and larva cases of some Australian Aphrophoridæ, by F. Ratte, M.E. This paper describes the larval state of some small species of *Rhynchota* closely allied to the genus *Aphrophora*, and belonging probably to the genus *Ptyelus*. They are as yet imperfectly known; but the description of their larva cases and of some of the larvæ discloses a feature probably quite new to the science of entomology. These cases, unlike those of insects generally, are true shells, containing at least three-fourths of carbonate of lime, and resembling in shape some fossil and recent serpules, some being conical, others serpuliform, or helicoidal. The conical shells are fixed on the branches of some species of Eucalyptus, the mouth turned upwards, the larva being placed in it with the head downwards. It introduces its suctorial apparatus into the bark of the stem, sucks the sap of the tree, and emits from time to time, by its anus, drops of clear water. This property of emitting water is possessed by all the family.

PARIS

Academy of Sciences, January 19.—M. Bouley, President, in the chair.—On the approximate degree of accuracy of the differential formulas employed in Paris, Lyons, Kew, &c., in the reduction of the meridian observations, by M. M. Lœwy.—Remarks on the nervous system and embryonic forms of Gadinia Garnotii, by M. de Lacaze-Duthiers.—On the existence of glycerrhizine not only in *Glycyrrhiza glabra* and *G. glandulifera*, where it was first discovered by Robiquet, but also in *Polypodium vulgare*, and several other families of plants, by M. E. Guignet. From a protracted study of this substance the author infers that it plays a great part in the vegetable kingdom, and is associated with the principal series of organic chemistry.—On the oscillations occurring at long intervals in machines set in motion by hydraulic agency, and on the best means of preventing these oscillations, by M. H. Léauté.—Statistical studies on the cholera epidemic in the Paris hospitals, and especially on the circumstances attending the outbreak in the Asylum for the Aged in the Avenue de Breteuil, by M. Emile de Rivière. From November 4, 1884, when it made its first appearance, till January 15, 1885, when the last patient was discharged, there were recorded altogether 1080 cases, of whom 636 were males and 444 females. Of these, as many as 587, or 54·15 per cent., succumbed, that is to say, 340 males, or 53·46 per cent., and 247 females, or 55·63 per cent. But in the Asylum, out of 215 inmates 79 were attacked (55 men and 24 women), and of these 65 perished (47 men and 18 women), or 82·278 per cent. This excessive mortality is attributed mainly to the great age of the pensioners in the Asylum, ranging from 58 to 90 years.—On the advantage of destroying the winter egg of Phylloxera in vineyards infested by this parasite, by M. Balbiani. The paper is supplemented by a note on the employment of a wash of sulphate of iron, by M. Faudran, who finds this remedy extremely efficacious in destroying not only the winter eggs, but also the insects adhering to the plant.—On Encke's Comet; observations made at the Observatory of Algiers with the 0·50m. telescope, by M. Ch. Trépied.—Supplement to two preceding notes on the theory of the figure of the planets and the earth, by M. O. Callandreau.—On the last results of solar statistics, by M. R. Wolf. The paper is accompanied by a table and diagram showing the number of days in each month of the years 1883 and 1884 when it was found possible to take solar observations at the Observatory of Zurich.

The author considers that a careful study of these tables will suffice to convince the most incredulous of the intimate relation existing between the solar phenomena (spots, faculæ, &c.) and the oscillations of the magnetic needle.—On some new transformations of partially-derived linear equations of the second order, by M. R. Liouville.—On the laws of evaporation as determined by the measurements recorded with ordinary evaporometers at the various meteorological stations, by M. Berthelot.—On oxygenated water, by M. H. Henriot. The results are given of experiments made to distil oxygenised water under a reduced pressure of 3 cm. of mercury.—On an easy method of obtaining measurable crystals of the peroxide of cobalt, CO^2O^4, by M. Friedel. The method consists in submitting the liquid chloride to the action of a current of moist air in the same apparatus in which he has already succeeded in obtaining artificial hausmannite.—On the formation of the nitrate of tetramethylammonium, by MM. E. Duvillier and H. Malbot.—On a method for regulating the chemical action of solar radiation, the intensity of which is constantly changing on the surface of the earth, by M. L. Olivier.—On the origin of the Microzymas and of the Vibrionians everywhere present in the atmosphere, in water, and the ground, in connection with M. Duclaux's recent communication, by M. A. Béchamp. The author argues against M. Pasteur that these germs are to be sought originally, not in the air, where they are disseminated by the winds, but in the ground and water, where they are deposited by the disintegration of the neozoic and palæozoic rocks, and by decomposing animal and vegetable matter of all sorts. He holds this, not as a mere hypothesis, but as a conclusion actually determined by strict experiment, by facts discovered by himself, verified and controlled by former opponents of his views.—Note on the vitality of the germs of microbes preserved in the liquid in which they were developed, by M. E. Duclaux. The persistence of these germs for a period of twenty or twenty-five years is clearly determined by the author's researches.—On some physiological phenomena associated with the lesion of certain parts of the animal organism, by M. H. de Varigny.—Contribution to the study of the glands yielding byssus, and of the water-bearing pores in the family of the Lamellibranchidæ, by M. Th. Barrois.—Remarks on some new crepuscular glows recently observed in Central America, by M. F. de Montessus.—On some of the phenomena observed in connection with the recent earthquakes in the south of Spain, by M. A. Germain.—Observations collected on earthquakes during a residence of forty-six years in Chili, by M. Domeyko.—Observations on the earthquakes that occurred in Andalusia on December 25, 1884, and the following weeks, by M. F. de Rotella.—Earthquake shocks felt at the Azores on December 22, 1884, by M. da Praia.

BERLIN

Physical Society, January 9.—Dr. Kayser reported on measurements of the electromotive force and of the resistance of an improved Noë thermo-generator, which in its essentials resembled the old Noë generator, differing from it only in that, instead of the wires connecting the bismuth alloy pieces with one another, strips of an unknown alloy were taken, which opposed greater resistance to heat than did the wires. The electromotive force of the generator increased proportionally with the quantity of the gas consumed for heating, that is, proportionally with the temperature. The curve of the electromotive force formed a straight line, and showed a bend only in proximity to the terminal temperature, where the metallic parts began to melt. The resistance of the generator, which, at the temperature of the room, amounted to about 0·9 Siemens unit, rose with increasing consumption of gas, reached a maximum of about 1·2 Siemens unit under a consumption of about 60 cc. gas per hour, and then, under a consumption of 100 cc. gas, sank below the initial value. On repetition of the measurement, the resistance was found to become less and the curve flatter. After a repose, however, of several days, the resistance again grew greater, without, however, reaching the value of the newly-examined battery. On a comparative estimate of the costs of generating electricity by means of a thermo generator and a Bunsen battery, it was ascertained that a current of 1 ampere per hour with the Bunsen battery cost about 3 pfennigs, but with the thermo-battery only somewhat over 1 pfennig. The current of the thermo-battery proved itself, in conclusion, highly constant, no change in the current having been observed in the course of twenty-four hours' uninterrupted heating with the Bunsen flame.—Prof. von Helmholz confirmed the last-mentioned fact. For the purpose of the electrolytic purification of quicksilver, he had made incessant use for a fortnight long of a thermo-battery, and on intercalating a galvanometer had discovered only inconsiderable variations in the current. He described the various methods he had made trial of, for the complete purification of quicksilver, all which, however, turned out ineffectual, till at last he adopted the electrolytic method, applying it in the following manner:—The impure quicksilver lay at the bottom of a glass vessel, and on the quicksilver swam a second vessel for the reception of the pure metal. An isolated platinum wire dipped into the quicksilver, connecting it with one pole of the battery, while the other pole was connected with a platinum plate placed in the empty vessel. The vessel then was filled with nitric acid, and the nitric oxide of quicksilver which was formed became decomposed by the current. The quicksilver separated itself, chemically pure, on the platinum strip, in the form of little globules, which dropped into the swimming vessel, and after covering the bottom in a cohering layer, it formed itself the electrode, at which the pure quicksilver further precipitated itself.—Prof. Neesen reported on a series of thermo-batteries and galvanic elements which had been quite recently patented for Germany, but which presented no innovations in principle. The only element deserving any special notice was Pabst's, consisting of carbon impregnated with oxide of iron, solution of chloride of iron, and iron, a material said to remain long constant for weak currents.—Prof. von Helmholz related that this cell had been sent to the Physical Institute, and for four months had proved itself pretty constant for weak currents. Following this up, he described the arrangement he had very recently given to the Daniell cell for the common purposes of the laboratory. At the bottom of a deep glass goblet lay a copper spiral connected with an isolated platinum wire in a glass tube. Above the spiral was placed a solution of blue copperas, which could be filled in by means of a funnel reaching to the bottom. On the solution of copper lay the lighter water-clear acid, or white sulphate of zinc, in which was placed the zinc cylinder. A siphon, the outer leg of which was directed from below upwards, dipped into the fluid as far as the bounding plane of the two fluids, so that, on filling in a fresh solution, only the solution of white vitriol immediately above the blue copperas, and contaminated by it, flowed off. This arrangement had the effect of keeping the upper fluid constantly water-clear, though, indeed, after a while, some copper was found precipitated on the zinc cylinder. The constancy, however, of the cell was not thereby perceptibly impaired.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1000 at £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share being given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the net Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being **£333,383**.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

THE "LOISETTIAN"
SCHOOL OF MEMORY.
INSTANTANEOUS MEMORY!
ART of NEVER FORGETTING!!
DISCONTINUITY CURED!!

A Physiological System, wholly unlike Mnemonics, using none of its "Localities," "Keys," "Pegs," "Links," or "Associations."

Dr. ANDREW WILSON, F.R.S.E., Editor of "Health," says:—

"PROFESSOR LOISETTE'S SYSTEM IS PHYSIOLOGICAL AND SCIENTIFIC IN THE HIGHEST DEGREE."

Mr. RICHARD A. PROCTOR, Editor of "Knowledge," in No. 117, dated January 25, 1884, says:—

"I HAVE NO HESITATION IN THOROUGHLY RECOMMENDING THE SYSTEM TO ALL WHO ARE IN EARNEST IN WISHING TO TRAIN THEIR MEMORIES EFFECTIVELY, AND ARE THEREFORE WILLING TO TAKE REASONABLE PAINS TO OBTAIN SO USEFUL A RESULT."

Any Book Mastered in *One Reading.*
Great Inducements to Correspondence Classes.
Prospectus post-free on application to
PROFESSOR LOISETTE,
37, NEW OXFORD STREET (opposite Mudie's Library), LONDON.

BROWNING'S PLATYSCOPIC LENS.

Engraved Real Size.

A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively, 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s.* 6*d. each power.*

Illustrated description sent free.

JOHN BROWNING, 63, STRAND, LONDON, W.C.

MACMILLAN & CO., LONDON.

NORTH BRITISH AGRICULTURIST,

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street, London, E.C.

Money Orders payable to CHARLES ANDERSON, Jun., Edinburgh.

On the 1st of every Month.

JOURNAL OF BOTANY,

BRITISH AND FOREIGN.

Edited by JAMES BRITTEN, F.L.S., British Museum.

CONTENTS:—Original Articles by leading Botanists.—Extracts, and Notices of Books and Memoirs.—Articles in Journals.—Botanical News.—Proceedings of Societies.

Price 1s. 3d. Subscription for One Year, payable in advance, 12s.

London: WEST, NEWMAN, & CO., 54, Hatton Garden, E.C.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations. Conducted by C. G. BARRETT, J. W. DOUGLAS, R. MCLACHLAN, F.R.S., E. C. RYE, F.Z.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s. each; the succeeding vols. may be had separately or together, at 7s. each.

London: JOHN VAN VOORST, 1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

PATERSON & COOPER,

76, LITTLE BRITAIN, LONDON, E.C.

Electric Light and Power and Telephone Engineers.

New Electric Light Catalogue, post free 1s.

PATERSON & COOPER beg to give notice that they have disposed of the Philosophical, Educational, and Experimental Part of their Business to Messrs. J. and T. MAYFIELD, 41, Queen Victoria Street, E.C.

HOLLOWAY'S PILLS

THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

PUBLISHED BY J. & A. CHURCHILL.

INORGANIC CHEMISTRY.

By EDWARD FRANKLAND, Ph.D., D.C.L., LL.D., F.R.S.,
Professor of Chemistry in the Normal School of Science; and
FRANCIS R. JAPP, M.A., Ph.D., F.I.C.,
Assistant Professor of Chemistry in the Normal School of Science.

With Lithographic Plates and Wood Engravings, 8vo, 24s.

VALENTIN'S QUALITATIVE CHEMICAL ANALYSIS. Edited by W. R. HODGKINSON, Ph.D., Würzburg, Demonstrator of Practical Chemistry in the Science Schools, South Kensington, Professor of Chemistry and Physics in the Royal Military Academy; and H. M. CHAPMAN, Assistant Demonstrator of Chemistry in the Royal School of Mines and Normal School of Science, South Kensington. Sixth Edition, much Enlarged, with 67 Engravings, 8vo, 8s. 6d.

PHYSICAL AND INORGANIC CHEMISTRY, founded on the well-known MANUAL of FOWNES. By HENRY WATTS, B.A., F.R.S. With Coloured Plate of Spectra and 150 Wood Engravings, Crown 8vo, 9s.

Also, Edited by Mr. WATTS,

FOWNES' MANUAL OF ORGANIC CHEMISTRY, or Chemistry of the Carbon Compounds. Twelfth Edition, Crown 8vo, 12s.

CHEMISTRY, INORGANIC AND ORGANIC. WITH EXPERIMENTS. By CHARLES L. BLOXAM, Professor of Chemistry in King's College, London. Fifth Edition, with 292 Engravings, 8vo, 16s.

AN INTRODUCTION TO PHYSICAL MEASUREMENTS: with Appendices on Absolute Electrical Measurement, &c. By Dr. F. KOHLRAUSCH, Professor in Ordinary at the University of Würzburg. Translated from the Fourth German Edition by T. H. WALLER, B.A., B.Sc., and H. R. PROCTER, F.C.S. Second (English) Edition, with 37 Engravings, 8vo, 15s.

THE MEDICAL DIRECTORY FOR 1885, giving the Names, Addresses, Qualifications, Appointments, Scientific Distinctions, Published Works, &c., of Medical Practitioners and Dental Licentiates in Great Britain and Ireland; also a List of Registered Practitioners Resident Abroad, and of those in the Army, Navy, and Mercantile Marine; with much General and Statistical Information relating to Medical Education and Practice. 1600 pp., 8vo, 21s.

A CODE OF RULES FOR THE PREVENTION OF INFECTIOUS AND CONTAGIOUS DISEASES IN SCHOOLS: being a Series of Resolutions passed by the Medical Officers of Schools Association, January 7, 1885. 8vo, 1s.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to Elucidate the Action of the Imagination. By DANIEL HACK TUKE, M.D., F.R.C.P., Editor of the *Journal of Mental Science*. Second Edition, 2 vols. Crown 8vo, 15s.

By the same Author,

SLEEP-WALKING AND HYPNOTISM. 8vo, 5s.

THE MICROSCOPE AND ITS REVELATIONS. By WILLIAM B. CARPENTER, C.B., M.D., LL.D., F.R.S. Sixth Edition, illustrated by 26 Plates, 500 Wood Engravings, and a Coloured Frontispiece. 900 pp., Crown 8vo, 16s.

By PROFESSOR BENTLEY.

THE STUDENT'S GUIDE TO SYSTEMATIC BOTANY, including the Classification of Plants and Descriptive Botany. With 350 Engravings, Fcap. 8vo, 3s. 6d.

THE STUDENT'S GUIDE TO STRUCTURAL, MORPHOLOGICAL, and PHYSIOLOGICAL BOTANY. With 600 Engravings, Fcap. 8vo, 7s. 6d.

A MANUAL OF BOTANY. Fourth Edition, with 1185 Engravings, Crown 8vo, 15s.

HANDBOOK OF MIDWIFERY FOR MIDWIVES. By J. E. BURTON, M.R.C.S., L.R.C.P. Lond., Surgeon to the Hospital for Women, Liverpool. Second Edition, with Engravings. Fcap. 8vo, 5s. 6d.

A MANUAL OF NURSING, MEDICAL AND SURGICAL. By C. J. CULLINGWORTH, M.D., M.R.C.P., Physician to St. Mary's Hospital, Manchester. Second Edition, with Engravings, Fcap. 8vo, 3s. 6d.

No. XCVII., JANUARY, with 12 Lithographic Plates, Price 10s.

THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.

Edited by E. RAY LANKESTER, M.A., F.R.S., F.L.S., Fellow of Exeter College, Oxford, and Jodrell Professor of Zoology in University College, London.

With the co-operation of W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Assistant-Director of the Royal Gardens, Kew; E. KLEIN, M.D., F.R.S., Joint-Lecturer on General Anatomy and Physiology in St. Bartholomew's Hospital Medical School, London; H. N. MOSELEY, M.A., F.R.S., F.L.S., Linacre Professor of Human and Comparative Anatomy in the University of Oxford; and ADAM SEDGWICK, M.A., Fellow and Assistant-Lecturer of Trinity College, Cambridge.

CONTENTS.

The Significance of Kupffer's Vesicle, with Remarks on other Questions of Vertebrate Morphology. By J. T. Cunningham, B.A., Fellow of University College, Oxford, Superintendent of the Scottish Marine Station.
Blastopore, Mesoderm, and Metameric Segmentation. By W. B. Caldwell, M.A., Fellow of Caius College, and Balfour Student in the University of Cambridge.
On the Origin of the Hypoblast in Pelagic Teleostean Ova. By George Brook, F.L.S.
On the Presence of Eyes in the Shells of Certain Chitonidæ, and on the Structure of these Organs. By H. N. Moseley, F.R.S., Linacre Professor of Human and Comparative Anatomy in the University of Oxford.
Archerina Boltoni, nov. gen. et sp., a Chlorophyllogenous Protozoon, allied to Vampyrella, Cienk. By E. Ray Lankester, M.A., F.R.S., Jodrell Professor of Zoology in University College, London.
On the Apex of the Root in Osmunda and Todea. By F. O. Bower, M.A., Lecturer on Botany at the Normal School of Science, South Kensington.
Correction of an Error as to the Morphology of *Welwitschia mirabilis*. By F. O. Bower, M.A., Lecturer on Botany at the Normal School of Science, South Kensington.
E. Van Beneden's Researches on the Maturation and Fecundation of the Ovum. By J. T. Cunningham, Fellow of University College, Oxford, Superintendent of the Scottish Marine Station.
On the Suprarenal Bodies of Vertebrata. By W. F. R. Weldon, B.A., Fellow of St. John's College, Cambridge, Lecturer on Invertebrate Morphology in the University.
On the Life-History of Certain British Heterœcious Uredines. (The *Ranunculi ficariæ* and *Puccinia schoeleriana*.) By Clarence B. Plowright.
On the Occurrence of Chitin as a Constituent of the Cartilages of Limulus and Sepia. By W. D. Halliburton, M.D., B.Sc., Sharpey Physiological Scholar, University College, London.

SIR HENRY COLE

Fifty Years of Public Work of Sir Henry Cole. Two vols. (London: George Bell and Sons, 1884.)

THIS book, though chatty and discursive enough in parts, will disappoint those who want to learn something of the personality and life of a doughty champion of some dozen reforms. The first part, from the racy pen of Sir Henry Cole himself, teems with lively comments and thrusts, *more suo*. The vigour of a man who believed in his mission, and rejoiced in the work of his own hands, appears on every page. No mark is required to indicate the transition from the dashing, animated narrative of the chief actor to the careful and cautious chapters written by his children. We do not see how either could give us what we chiefly want without offending against certain rules of delicacy which we are glad to know are not yet quite obsolete. The life of Sir Henry Cole, the inner history of his struggles, his successes and failures, the motive power, and an impartial view of the man in relation to his work—this has yet to be written. What he and his children between them have given us is a valuable collection of facts and documents bearing upon the most important progressive movements of our century.

To not a few the second volume will be more interesting than the first. The plan of the work is to give in the first volume a series of chapters which take in Sir H. Cole's principal work, and the corroborative and supplementary documents, with many curious illustrations, make up the second volume. The whole concludes with a most thorough-going verbal index, which would have rejoiced Sir Henry Cole's heart, for to him nothing was complete without an index.

Henry Cole had to face no ordinary difficulties in carrying out his work, but then he was just the man for difficulties. He would have been nowhere in piping times of peace. His appetite for a task grew as the opposition and hindrances grew. Probably no one ever knew him to be faint-hearted or broken in resources. At last it came to be felt that he would in any case carry his point, and timid natures gave way before the impetuosity of a knight whose sword had no scabbard, and who left himself no retreat. You could only beat him by cutting him to pieces—there was no other way. At the Paris Exhibition of 1855 he was known to the officials as *ce terrible Cole*—a man who, regardless of the methods of red tape, took the shortest way to his point, and did not know when he was beaten by all the rules of officialism.

Associated with this indomitable pluck was another quality which the English people love well. He had a never-failing flow of good spirits which burst forth in rollicking good humour, confusing and sometimes irritating to his opponents. We suspect that not a few of the enemies he made had suffered in their self-esteem from the sharpness of his common sense driven home by his reckless love of fun—at least of what was fun in him. Once, when giving an address, in a provincial town, on public libraries, as he was advocating the setting up of reading-rooms where smoking would be allowed, a local magnate on the platform testily interrupted him with a formal protest and the remark that there was a public-house across the road. Sir Henry Cole, pausing in his discourse, surveyed his critic for a moment with a curious air, and then, turning to the audience, said in a loud "aside" and with the most perfect good humour:—"This gentleman seems to be a kind of pope down here." The cause of his antagonist collapsed amidst inextinguishable laughter. On another occasion the Education Code was under consideration, and one, not remarkable for hereditary wisdom, suggested that the poor children should be taught "legal economy," meaning thereby, as was explained, a knowledge of the laws of the land,—"And the Ten Commandments," interpolated Sir Henry Cole in a stentorian voice. People do not readily forgive such setting forth of their folly, but it was a temptation which an impulsive enthusiast could not resist.

In the short space allotted to this notice it would be unwise to indulge in extracts. If we take one, it is because it sets forth in Sir Henry Cole's own words the works of a public nature with which he was connected.

"The principal subjects which I now deal with are the reform of the system of preserving the inestimable public records of this country, dating from the time of the Norman Conquest, and unrivalled in Europe; my work in expediting the successful introduction of Rowland Hill's penny postage; the administration of railways; the application of fine art to children's books and then to manufactures, which led to the transfer of my duties to the Board of Trade; the Great Exhibition of 1851, and its successors; the reform of the Patent Laws; the establishment of schools of art and science classes throughout the United Kingdom; the South Kensington Museum; drill in public elementary schools as the basis of a national army; national training schools for music and for cookery; the Society of Arts, and public health."

To begin with the public records. Entering this office as a mere youth, his spirit was stirred within him when he saw the utter carelessness as regards documents "dating from the time of the Norman Conquest and unrivalled in Europe." For daring to call attention to the jeopardy in which these precious records were placed he was dismissed, and no doubt it was thought the insignificant youth was extinguished; but in the end young Cole dragged the affair before Parliament, and was triumphantly reinstated with something like full powers to carry out the much-needed reform. Our Public Records Office is now a credit to the administration of the country, but fifty years ago (so it was stated in Parliament) public records were boiled down for glue, and the clearer and better sort converted into jellies by the confectioners (Mr. Charles Buller's speech on Public Records, vol. ii. p. 86).

While at the Records Office, Henry Cole threw himself into the uniform penny postage movement. The particular task he undertook was to rouse popular enthusiasm for the reform, and we have Sir Rowland Hill's testimony that "he was the author of almost innumerable devices by which in his indefatigable ingenuity he contrived to draw public attention to the proposed measure." There is an amusing cut in the book (vol. ii. p. 102) representing one of these devices. Mr. Cole obtained a prize of 100*l.* from the Treasury for an essay on the best method of

carrying out some parts of the reform, and ultimately he was taken from the Records Office to assist in remodelling the postal system.

His next dealings were with railway administration, and he took part in the "battle of the gauges," but this work was, we should think, somewhat out of his line. It is dull and heavy reading after the fun and energy shown over postal reform. At length he emerges from dealings with railways and docks into the more pleasant paths of art. Under the *nom de plume* of Felix Summerly he produced handbooks on art. In this connection he threw himself into wood-engraving, and so "mastered the technicalities of etching on copper that my works obtained admission (vol. i. p. 103) to the Royal Academy." In Summerly's handbooks, also, essays in bookbinding were made, and the beautiful designs of Holbein, as well as the fifteenth century patterns for leather still remaining in Durham Cathedral, gave suggestions which were used. The Summerly tea-service, which won a prize offered by the Society of Arts, is still much admired. An engraving is given in vol. ii. p. 178. Out of his work under this head sprang his connection with the Board of Trade and their School of Design.

Henry Cole as Felix Summerly strove to "make art common"—a reproach he would have accepted joyfully. Assisted by the best art of his day, he produced artistic books for children, prepared descriptive catalogues of the art treasures of the country, and endeavoured to realise Gibson's ideal panel, in which is represented the marriage of Art and Commerce. His next move in this direction was to persuade the Society of Arts to get up a national exhibition of British manufactures. Prince Albert was the active President of this Society. It was he who developed the idea into a universal exhibition—the Great Exhibition of 1851. At this part the notes are particularly full. It is as if Henry Cole had never done anything remarkable before or since. If this gigantic undertaking was a gigantic success, the credit is largely due to the energy and ability of Henry Cole, who was rewarded with the decoration of C.B.

The work of the Great Exhibition and the other exhibitions which followed interfered for a while with the development of the two greatest undertakings of this busy creative life. We refer to the South Kensington Museum and the Science and Art Department. The Museum stands by general admission first of such institutions. Here the designer and the artisan may study a vast collection of the products of human ingenuity. The idea seems to have sprung naturally from the Great Exhibition of 1851. If such a show be good for the development of manufacturing and mechanical ingenuity and for creating artistic taste, why not have one in permanence? When the question arose what was to be done with the surplus profits of the Great Exhibition, it occurred to the Prince Consort and the Executive to found a museum for a permanent exhibition. Accordingly, on accepting from the Board of Trade the task of reforming art instruction throughout the land, Cole recommended the purchase of art objects from the Exhibition. The usual objections of red tape stopped the way for a time, but the indefatigable reformer, backed by the Prince Consort and Lord Granville, triumphed as usual, and a Committee was appointed to spend a sum of 5000*l*. This transaction is the real origin of South Kensington Museum. The collection then purchased (1851) was the nucleus of a museum of art manufactures "which should have its connection through the whole country and help to make the schools of art as practical in their working as those of France and Germany" (vol. i. p. 283). We may here remark that though there is a circulating department at South Kensington Museum it is by no means in a forward state. A few pictures are lent for six weeks at a time to local schools of art, and whenever an exhibition is got up, South Kensington contributes specimens with not too liberal a hand; but Mr. Mundella has promised more, though in indefinite terms. Wherever a local museum is maintained in fair efficiency there should be a division supplied continuously from South Kensington. It is not enough to wait for local action. The department should invite applications and raise public attention by means of a letter (not circular) sent now to this mayor and now to that. The subject would then probably be brought forward in the Town Council and discussion and inquiry would result. This proceeding would be dreadfully unofficial no doubt; but South Kensington, which inherits the traditions of a sagacious chief, is perhaps the most *human* of all government departments. It can stoop to consider ideas from outside. Possibly steps have been already taken in this direction as regards the Liverpools and Birminghams of our land. The writer's experience with much smaller towns has led to the conclusion that *temporary* aid of the kind above indicated is much needed in the interests of art development; *temporary*, for with regard to the Government and local effort, the aim should be to throw the dependency as soon as prudent on its own resources. First the child is nursed and coddled, then he is placed "under tutors and governors," who harden him off, and at last he is left to manage for himself and to pick himself up when he falls. A vigorous son of the north, whose heart was in this work, laid this down as the best policy: "First a stick and then a kick." It is remarkable, indeed, how small a part of the aid given by the Government reaches the institution for which it is intended. For scientific apparatus teachers have again and again gone into the open market and done better than with the Government aid of 50 per cent. through accredited agents. In books we have known a great part of the aid given by the Science and Art Department to be swallowed up by insufficient deduction from the published price and by unusual charges for packing. The supply of art specimens also is faulty in this respect. It is probable that competition would not permanently remove these objections. The Department should in our opinion *give*, and give not needful things but accessories—not the beef but the condiments—and having thus evoked a more cultivated appetite should leave it to seek its own gratification.

Those who wish to know with what painful steps and slow the magnificent collection at South Kensington was got together, will find full particulars in the latter part of the first volume of this interesting memoir. It was started at Marlborough House, beginning with the art specimens which had been collected for the old Schools of Design and the purchases from the Great Exhibition. Subsequently, grants were made by Parliament for purchasing specimens of artistic specimens of all ages, and the never-

to-be-baffled Director gave his superiors no peace, and probably would have been equally importunate and equally unsatisfied if he had reached the age of Methusaleh. This worrying may have been very unpleasant for the political heads of the department, but it has been a good thing for the country. Whoever visits South Kensington Museum and profits by his visit should bless the pertinacity of Henry Cole. Not only the Government was waylaid, but the Queen and Prince Albert, and other collectors and possessors of art objects were invited and persuaded to give the public an opportunity of seeing them for a time in the Museum. Loan exhibitions of furniture, &c., were formed, and photographs, casts, and electrotypes were made of the finest objects which thus came temporarily into the possession of the Museum. This system of reproduction has helped to develop immensely certain divisions of the Museum, and is likely to be of immense benefit to museums generally. Witness the splendid electrotype reproductions of Corporation and College plate in South Kensington Museum. Purchases were made from the Bernal Collection and that of M. Soulages was added to the treasures of South Kensington after an intricate series of negotiations. The pictures which the Rev. John Sheepshanks bequeathed to the nation also found a home here, but his desire that they should be on view for the working people on their day of rest has not been respected. The Editors note the condition on which the bequest was made, and dryly add that after the arrival of the collection at South Kensington it was inspected on many successive Sundays by members of the Legislature and their friends, but it was hardly their Sundays in particular that this public benefactor desired to refine and brighten. South Kensington Museum succeeded to Marlborough House in 1857, and it continued under the rule of "King Cole" till 1873, when he retired on full pay, not altogether willingly, we believe. No doubt he was a despot, but in the early stages of unique institutions a despot is necessary. As it stands, South Kensington Museum is a lasting monument of his foresight, his delight in work, and zeal for the material prosperity of his country.

But the Science and Art Department is Sir Henry Cole's greatest work, and the greatest monument of his genius. How he kept on teasing the Government for money and spending more than was allowed, till at last he had put together a noble collection, and the Museum was a fact—this is generally known; but the history of the Science and Art Department has yet to be told. It was conceived and constructed by a dogged inventive genius which knew how to turn difficulties into stepping-stones to success, and to wear out stolid opposition by vivacious pertinacity.

This Department was formed as a branch of the Education Department, with Henry Cole as its head, its hands, and its feet, under the nominal control of the successive Presidents and Vice-Presidents of the Privy Council. These statesmen we will venture to say had little idea of what was being done in their name. The grants which the manager was able from time to time to obtain were utterly insufficient for ordinary lines. We know the old jog-trot idea which a commonplace mind would have formed: First, to train teachers, and then to found and maintain schools in the different towns of the land; but Cole's plan was to bribe teachers to qualify themselves by promising them payments on the results of examinations in various centres supplied with papers from London to be worked out under local committees at a minimum of expense. Soon the land was covered with schools of art and science classes, to the astonishment of the statesmen who supposed that they had been holding the reins. As a result, the English people were converted from Philistinism, and became ardent lovers of art. In the poorest cottages may now be found vessels of artistic design and other delights of the eye, as cheap as the ugly patterns which obtained everywhere except in the houses of the richest a few years ago. In the recent debates in the French Parliament on the proposed renewal of the Commercial Treaty with England, the French Minister stated that when that treaty was first made, in 1859, France supplied England with almost all its objects of art, but that in the interval, owing to the work of the schools of art, the tables had been turned, and it was now England that was pouring these articles into France. It was *ce terrible Cole* who had stuck to his work, undeterred by abuse and opposition, till he had redeemed England from its dependence on the ingenuity of France.

Sir Henry Cole's retirement from office in 1873 did not mean retirement from work. Out of office, he set himself to do for music and cookery and sanitation what he had largely done for art, namely, to make their principles and practice common and popular. He pictured an England whose toilers, admitted to participate in the benefits of civilisation, found relief in refined enjoyments from the depression resulting from the minute division of labour into dreary monotonous tasks, without variety. The part he bore in establishing the Kensington Training School of Cookery and the School of Music, and his share in promoting the Albert Hall, will best show the earnest work of his later years. His work and his life in fact ceased together.

Whoever will read the list of the tasks which Sir Henry Cole set himself, as enumerated at the beginning of this article, will not find it hard to discern running through the whole of this busy aggressive life one constant, continuous idea. Like the great English reformer who vowed that he would make things plain for a ploughman which had been reserved for the understanding of a cultivated few, Henry Cole lived to make the poor sharers in the best benefits of modern civilisation. He set himself to make common those refining agencies which tend to cheer and sweeten the dull monotony of excessive toil and hopeless poverty. Hence his efforts to stimulate the creative faculties of the nation, to make known our art treasures, to cheapen specimens of art and to call out the dormant sense of delight in the beautiful, so as to reach and raise men through their higher faculties of enjoyment. He who sets himself to "level up" and to destroy privileges by making them common will have enemies enough in his time. Probably Sir Henry Cole had his full share of abuse and misrepresentation. But, unlike many of the world's benefactors, he lived to see much good fruit resulting from his pertinacious toil for the public good, and he will not soon be forgotten by a grateful country.

NEWTON PRICE

EARTHQUAKES AND FIRE-DAMP

On the Observation of Earth-shakes or Tremors in Order to Foretell the Issue of Sudden Outbursts of Firedamp. By M. Walton Brown. Excerpt Minutes of Proceedings of the North of England Institute of Mining and Mechanical Engineers, vol. xxiii. 1884.

A Theory of Mine Ventilation. By M. Walton Brown. (Printed by Lambert and Co., Limited, 50, Grey Street, Newcastle-on-Tyne, 1884.)

THE first of Mr. Brown's two papers contains a proposal to institute the systematic observation of earth-tremors for purposes which he describes as follows:—

"Whatever may be the cause of the issue of sudden outbursts of firedamp the quantity of gas produced is extremely variable and irregular. Many theories have been from time to time advanced with the object of defining the laws which govern these sudden outbursts of gas from coal and adjacent strata.

"It would appear that there is some connection between sudden outbursts of gas and the motions to which the crust of the earth is subject: in other words, that slight motions of the earth's crust may be followed by more or less violent outbursts of gas. Thus, if there were a large body of gas pent up in a subterranean reservoir, and some movement of the earth's crust took place forming fissures of varying depth and width, affording channels for the escape of this gas, upon such a fissure being reached in the workings of the mine, a blower would be the result, the volume and duration of which would depend upon the volume of the reservoir, pressure of the gas, and width of the fissure. If this theory is the true solution of the problem, it follows that the systematic and regular observation of earth movements would eventually prove a reliable means to some extent of foretelling when outbursts of gas should be anticipated."

If gas existed in subterranean reservoirs such as those imagined by Mr. Brown, then, undoubtedly, when the workings of a mine reached a fissure communicating with such a reservoir all that Mr. Brown anticipates would happen. Supposing it possible, however, that a fissure could be formed by an earth-tremor at the depths at which firedamp exists in a sufficient state of tension to give rise to an outburst when tapped, it does not by any means follow that the observation of earth movements could assist us in foretelling when such outbursts would be likely to happen. For the position of any given fissure, relatively to that of the workings, must obviously be an unknown quantity, so that, for anything we could know to the contrary, the fissure might either be broached on the day of its formation or not for many years afterwards.

This paper is illustrated by two plates: one, a seismographic map of Western Europe, showing the distribution of earthquakes, copied from the map prepared by the Messrs. Mallet; the other a diagram showing, by curves, the relative frequency of earthquakes and fatal explosions of firedamp, and the mean height of the barometer monthly from January of one year to April of the following year. The explanation of the second plate appears to be incomplete. As regards the barometric curve this a good opportunity of remarking that correlate mean barometrical observations extending over longer periods than a few hours with explosions in mines appears to us to be labour lost, and similarly we are satisfied that the bald statement so often met with, that the barometer was rising or falling at the moment any particular explosion happened, is devoid of value, and leads simply to confusion. This subject was most carefully investigated by Mr. R. H. Scott, F.R.S., and the writer some years ago, and the results were published in various papers at the time (*Proc. Roy. Soc.*, 1872; *Quart. Journ. Met. Soc.*, 1873 and 1874). The diagrams which accompany these papers show very distinctly that the barometric curve ought to be known accurately for several days before the occurrence of an explosion if it is desired to form a true opinion as to the probable influence of atmospheric agencies in the case.

In his second paper Mr. Brown does good service by calling the attention of the English reader to the manner in which the problem of ventilating mines has been simplified by the recent researches of M. Murgue, the able director of the Bessèges Collieries in France. M. Murgue's articles were contributed to the *Bulletin de la Société de l'Industrie Minérale*, second series, vols. ii., iv., and ix.; and his views are also very clearly set forth in the second volume of M. Haton de la Goupillières's excellent and concise "Cours d'Exploitation des Mines," just published.

It is evident from the nature of the case that the details of no two mines can be exactly alike as regards the resistances which they oppose to the circulation of ventilating currents through them. The diameter and depths of the shafts, the lengths, areas, bends, ascents, and descents, and comparative roughness of the sides, of the air-ways, the temperature, tension of water vapour, and the velocity of the air-currents, must all vary with every varying circumstance. Accordingly, any attempt to compare the total resistance of one mine with that of another by finding the value of each element in the calculation and summing up the results could produce nothing but complication and disappointment.

M. Murgue has solved the problem by referring the sum total of all the resistances to one single and very simple resistance, namely, that of an orifice in a thin plate, which he calls the *equivalent orifice*. He describes it as *the area in square metres of the orifice through which the same manometrical depression will cause the same volume of air to pass in the same time as in the mine.* This area is found as follows:—Let a be the area required, q the quantity of air, v its velocity in passing through the orifice, and 0·65 as the value of *vena contracta* Then—

$$q = 0{\cdot}65\, a v.$$

Taking w the specific gravity of the air (estimated by M. Murgue at 1·2 kilo. per cubic metre), and h the manometrical depression (expressed in kilograms per square metre, or, what is the same thing, in millimetres of water), we have:

$$h = w\frac{v^2}{2g}, \text{ or } v = \sqrt{2g\frac{h}{w}},$$

whence

$$q = 0{\cdot}65\, a \sqrt{2g\frac{h}{w}}.$$

Then by introducing the numerical values of w as given above, and of g as 9·8088 metres, we get—

$$q = 2{\cdot}63\, a \sqrt{h},$$

whence

$$a = 0{\cdot}38\, q\sqrt{h}.$$

But we can always ascertain by observation the values of q and h in any given case, so that the value of the equivalent orifice can be easily found.

M. Murgue has determined this value for a large number of mines and has given the results in tables in his second article, already referred to. The values vary somewhat above and below a square metre, but a large number of them are very little different from that unique area. The author calls those mines whose equivalent orifice is greater than a square metre, *wide*, or roomy, and those in which it is less than a square metre, *narrow*, or confined.

M. Murgue has applied the same mode of comparison to the resistances which the air has to overcome in passing through the various kinds of ventilating machines, and in this case he distinguishes the corresponding orifice by the name of *orifice of passage*. The manner in which its value is found is similar to that of the equivalent orifice.

In Mr. Brown's paper will be found a table containing a summary of experiments made, with six different kinds of ventilators, by a Committee of the Société de l'Industrie Minérale, in which the translator has reduced the French measures to their English equivalents. He also gives two diagrams: one showing the volumes of air produced by the same ventilators kept running at a uniform velocity, while the equivalent orifice is gradually increased; the other showing the curves of useful effect for four of them. On the whole, we consider that the contents of this paper deserve the careful consideration of those who have not an opportunity of consulting the original articles. W. GALLOWAY

MAGNETO- AND DYNAMO-ELECTRIC MACHINES

Magneto- and Dynamo-Electric Machines. From the German of Glaser de Cew, by F. Krohn. Specially Edited, with many Additions, by Paget Higgs, LL.D., D.Sc. (London: Symons and Co., 1884.)

THIS book is issued as Volume I. of "The Specialists' Series," to be edited by "Dr." Paget Higgs and "Professor" Charles Forbes. From what University Mr. Higgs holds his degree of Doctor of Science does not appear. Presumably, he is the same person as the "Rev. William Higgs, M.A., D.D.," who formerly edited an electrical periodical in London, and afterwards left his country. Readers of the admirable volume on the "Transits of Venus" in the *Nature Series* know the name of Prof. George Forbes, and appreciate his scientific standing. They are not likely to confound him with the Mr. Charles Forbes who appears as joint editor.

The present volume, translated and "specially edited," gives to the public little that it did not previously possess. Of books on electric lighting there are enough and to spare. Dr. Schellen's work on "Magneto- and Dynamo-Electric Machines"—an excellent translation of which is now appearing in New York—was the first good work of the kind, and it has run to a second edition. In title and in matter it is greatly resembled by the present work; but Schellen's work is far more elaborate and complete; whilst the one merit of the Glaser-de-Cew-Krohn-Higgs-Forbes volume is that it includes a brief chapter on accumulators—too brief, considering that the various types are well and concisely explained. For the rest, the additions are chiefly scissors and paste work. Chapter VII., on Constructional Laws, is largely taken from Prof. S. Thompson's "Cantor Lectures"; Chapter VIII. gives the old set of tests executed for Trinity House in 1877 on obsolete types of machine; the only addition, relating to the later and far more perfect tests made at Paris in 1881, Munich and Crystal Palace (London) in 1882, and Vienna in 1883, being an editorial footnote five lines in length. Chapter X. is extracted from Du Moncel's book on "Electromagnets"; Chapter XI. (on Instruments for Measurement) is apparently amplified from the price list of a certain firm of electrical engineers, whose instruments, exclusively, are described. Chapter XIII. is an abridgment of Clausius' theory of the dynamo-machine, reprinted *verbatim* from the abstracts from foreign journals in the *Proceedings* of the Institution of Civil Engineers. The index is most elaborate: it occupies nearly a twelfth of the whole book. There are several glaring errors in the work. Of these is the statement, on p. 100, that in a compound-wound dynamo—in which it is desired to provide a current varying exactly proportionally to the number of lamps that are connected to the mains—there must be maintained "a constant magnetic intensity." On p. 143 it is elaborately set forth that the ratio of the part of the effective electrical energy which is converted into real work to the total electric energy of the current can "never be greater than ¼"; and on p. 147, equally elaborately, that "the maximum efficiency of an electro-generator is obtained when its internal resistance is equal to the resistance in the external circuit." If the latter statement were true the maximum efficiency could never exceed ½. The fact is that both statements are untrue and misleading, as are several of the statements relating to efficiency on p. 144. Apparently, either the translator or the editor does not understand either the English meaning of the German word *Nutzeffekt*, or the technical meaning of the English word *efficiency*. On p. 173 the shifting of the neutral point in the rotating armature is referred to the alleged fact (?) that "the magnetism of the iron core and the current in these turns of wire (which have passed the poles) remain at the same intensity for a few moments." The statement is misleading, and the supposed explanation of the shifting of the neutral point is well known to be a fallacy. Still more extraordinary is the statement made, apparently with scientific seriousness, on p. 174, that the heating of the iron core of the armature is another "consequence of the fact that the maximum magnetism does not immediately disappear." There are several mistakes in the definitions of the electrical units as given in the last page of the preface. The *watt* is given as the unit of *work*, instead of the unit of activity; and the extraordinary statement is made that the untit of potential difference "exists between two points when the unit quantity of electricity, in moving from the one point to the other, *requires a unit force* to overcome the electrical repulsion," thus making the definition of potential depend on *force* instead of *work*. Moreover, the static units are called the "C.G.S." units

without any mention of the magnetic units of the C.G.S system, leading the reader to conclude that the *volt* is equal to 10^8 of the static C.G.S. units. These are grave errors in a book designed for specialists. On p. 94 the author, or editor, announces the insertion of some "data given . . . *by physicists known for their veracity.*" Are there any others?

OUR BOOK SHELF

Key to Magnus's Class-Book of Hydrostatics and Pneumatics. (London Science Class-Books.) By John Murphy. 67 pp. (London: Longmans, Green, and Co., 1885.)

MR. MURPHY has rendered useful service to science teachers by the publication of the solutions of the exercises and problems given in Mr. Magnus's widely-known volume. These problems cover the whole ground of elementary hydrostatics and pneumatics; and the solutions are intelligently worked out in full. The work has had the benefit of Mr. Magnus's own revision; and this should be a guarantee of the goodness of the methods followed and of the correctness of the results. The only fault we have to notice is a tendency to looseness in the use of certain terms about which there ought not in physical science to be the slightest vagueness: we refer to the misuse of the words *strain* and *pressure* where the proper word should be *force*. A strain is an alteration of shape or volume, and ought not to be confused with the force which produces the strain. A pressure is a force divided by an area and cannot be specified except by naming both the force and the area on which that force acts. Yet on p. 5 of Mr. Murphy's Key occurs the statement that "the pressure or whole strain to which the sphere is subjected equals the weight . . . of the liquid." It is greatly to be desired that this ambiguity between pressure and force should as speedily as possible be removed from this and all other elementary books, as it is misleading to beginners as well as incorrect.

Electrical Units. By Dr. R. Wormell, M.A. (London: T. Murby, *no date.*)

THIS little work of 48 pp. is apparently issued as an appendix to the author's class-book of "Electricity and Magnetism." It contains a concise and easy account of the units in ordinary use, and of the notion of dimensions of units so puzzling to beginners. A number of useful data of constants are given, and there are some numerical problems for calculation added. Dr. Wormell's genius as a teacher comes out in several points: the transition from magnetic to electro-magnetic units being particularly neatly brought about on p. 19. A few slips should be corrected at once. In the table on p. 1 the electro-chemical equivalent of hydrogen is given as '00001055, and on p. 14 as '0000105. According to the late results of Kohlrausch and Lord Rayleigh it is '00001035. On p. 6 the horse-power is wrongly stated as 746 kilogrammemetres per second. On p. 15 there is a curious muddle about units of capacity, arising partly from a confusion between electrostatic and electromagnetic units. It is certainly *not* true that a sphere of one centimetre radius has a capacity about equal to that of "the whole Atlantic cable"; neither is the *farad* the millionth part of the *microfarad*. It also must strike the practical electrician as rather a curious statement that (p. 33) the Swan lamp is usually fed by the Gordon dynamo. We were under the impression that only one Gordon dynamo had yet been built, and that it had not been used since last winter. The connections of the Brush armature on p. 37 are wrong; and the author should not describe Edison's armature as being like that of Gramme, when the fact is that it pays royalty to Siemens as a Siemens armature.

Weekly Problem Papers, with Notes, intended for the Use of Students Preparing for Mathematical Scholarships and for the Junior Members of the Universities who are reading for Mathematical Honours. By the Rev. J. J. Milne, M.A. (London: Macmillan, 1885.)

MR. WALTER BESANT in a recent work entitled "In Luck at Last," makes his heroine (a Maria d'Agnesi or a Somerville) remark, "No life can be dull when one is thinking about mathematics all day. Do you study mathematics?" For such a one this handy volume of a hundred papers, each of which has at least seven questions, some of which bifurcate or trifurcate, will be a charming companion. Though the range is limited to the requirements of a University scholarship—this by the way is fairly extended at the present day—yet there is sufficient "variety" in the selection of problems to make it what we state it to be above, "charming." The book, as such a work ought to be, has been printed with very great care, and, after a close perusal, we have detected only two or three slight clerical errors. The compiler, who is to be congratulated on his successful achievement of a somewhat difficult task, proposes to bring out at a future date a second volume containing his solutions to the exercises. Wolstenholme's collection is, except under the guidance of a judicious tutor, too hard and too full of tricks for the class whose wants this manual is designed to meet; the boy who has mastered this collection, or a fraction of it, will have realised what sort of questions he will be called upon to "tackle" when he has an examination paper before him.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Free Hydrogen in Comets

TOWARDS the end of an admirable mathematical paper on the theory of the forms of comets, received this morning by post from M. Bredichin, that very able Director of the Imperial Observatory of Moscow (specifying himself, to us, in English as the head of a pamphlet in the French language as "Associate of the Royal Astronomical Society"), draws the conclusion that the great comet of 1881 was a structure of compound hydrocarbon gas, while Halley's historic comet was "of a type which corresponds to pure hydrogen."

The distinguished author's position with regard to the comet of 1881 I presume will be contested by no one; for all the spectroscopes of the time proved so abundantly that the light of that comet was of the kind familiarly known among terrestrials as "the candle-spectrum," or the spectrum of the compound gas CH, in the form of acetylene, perhaps, but already peculiar to carbo-hydrogen. Who, however, can help the theorist of Moskva's white-stoned city and golden domes to establish the probability of a spectrum of pure and elemental hydrogen gas for Halley's comet, before that wanderer in far off space shall return in the beginning of next century, and then instantly testify its chemical composition to the spectrum analysis of that day?

One of the difficulties which M. Bredichin has to deal with meanwhile, seems to be, that no trace of a pure hydrogen spectrum has ever yet been seen in any comet, however much of CH there may have been; and he is driven to suggest that the H, or hydrogen lines—so entirely different from those of CH—were invisible on account of their faintness. But though that idea, with some modification or explanation, may ultimately turn out to be correct, it requires something more just now to create many converts to it, particularly in face of the universal experience of all dabblers in spectroscopy with vacuum tubes; for they know so well that, whatever the reputed gas in them may be, intrusive lines of hydrogen, though present as an im-

iable impurity only, are usually the most incisive and brilliant
of the display.
a paper, however, on "Micrometrical Measures of Gaseous
ra," kindly printed, but not yet published, for me by the
l Society, Edinburgh, there is a full description of a case
will be found to supply exactly the practical details that
trengthen M. Bredichin's views.
er having had tubes, and tubes, and tubes again of CH
f various varieties of CH and at various pressures made
ferent makers, and having found their CH spectrum (under
ectrical incandescence which M. Bredichin also assumes for
mets) always more or less imperfect and more and more
sil, often overpowered, by the brilliant lines of pure hydrogen,
wed out the indications of least failure by eventually having
a so-called vacuum, but really four inches of mercury
re tube of olefiant gas. It was constructed for me, with
peculiar attention to, and precautions for, purity, by
harles F. Casella, of 147, Holborn, and attained absolute
s at last, for no trace of any impurity whatever could I
er in it from one end of the spectrum to the other.
only so, too, but the spectrum which it did show was the
rilliant and perfect one of CH that I have ever heard of.
one knows the five diversely coloured bands of CH, four
m first well described by Prof. Swan in 1856; each band
ing towards the red with strong lines and bright haze,
fades off towards the violet side into black, vacant space
efore the next band begins. And many persons know
ith greater spectroscopic power that haze is capable of
resolved into a system of smaller lines, and far closer, or
, but still coming to an end considerably short of where
et band begins.
on this occasion, with the extra heavy olefiant gas-tube,
induction sparks, and a spectroscope having 24° dispersion
to H of solar spectrum, a telescopic magnifying power
a very narrow slit and excellent definition of prisms,
lets, usually so difficult to identify, were as sharp and
luminous needles, and continued, in a series of regularly-
ing spaces apart, the whole distance from one CH band
next. This completeness was distinctly proved, first with
nge band and its needle-like scale of linelets (after all
ng lines had been left behind), extending up so as to
as it were, the brilliant beginning of the Citron band.
ame *fit* bright lines and closely-packed linelets continually
g in distance apart, but losing nothing in sharpness and
on until the Green band was reached. With the Green
as its leader (the so-called "Green Giant of Carbo-
n") burning like a pillar of electric fire; then its close
; then its second line and linelets rather wider apart;
line and linelets still wider; and onwards linelets wider
preserving admirable regularity of series all the way,
long way, without missing, or blurring, one step, the
istance right up to the beginning of the Blue band.
ver one pair of that lengthy road something extraneous
ear; vaguely at first, or as a mere faint ghost of a
perceptible roll of gray-coloured cirrostratus cloud!
d be subjective only? possibly the reflection from a
part of the retina of the observer's eye. Not that,
linelets of CH were still brilliantly sharp, thin, and
verywhere. What then? I, who had condemned scores
n tubes of all the gases for being filled with H lines,
r seen anything like that floating, filmy cloud before!
ought is quicker than sight. A suspicion of the truth
n a moment upon me; and on turning to the Red end
pectrum, there, over the known place of Hydrogen's
, was another faint broad region of barely visible
haze, but reddish, in place of, like the other, a blue-
ven, too, as I watched them, from that moment on
an hour, first turning to one and then to the other,
o-clouds narrowed and narrowed towards their central
whilst the sharp little linelets of the CH *pari passu*
ater and paler, until at last they only remained visible
ighbourhood of the bigger lines and strong beginnings
respective bands. And by that time the once faint
se red and the gray, had become transformed into two
bright lines of Hydrogen light, the representatives of
and Solar F; while the carbon of the CH, which the
en eliminated from by the action of the electric spark,
ited on the inside of the tube as a brown glaze.
then, is the case of independent observation which I
nd over to M. Bredichin for discussion, believing it to
that

(1) In the condition most suitable for showing the CH, or ordinary cometic, spectrum,—no H should appear.

(2) If a little fine H should be introduced into a full atmosphere of CH, the characteristic lines of H are at first *more* broadened—though seen under the same circumstances that those of CH are *ultra* narrow and defined in—as to be weakened thereby below visibility, unless, indeed, the CH spectrum at the time be almost infinitely brighter than it has ever yet been found in any Comet.

(3) The longer the incandescing electric influence is at work, the greater is the evolution of pure H on one side, and deposition of solid C on the other, out of CH gas. Whereas we may possess for the future an indicator for the comparative age of Comets; or, at least, may pretty certainly conclude Halley's Comet to be older than that of 1881, if bright, narrow lines of pure H, with or without CH bands accompanying, shall be visible in the spectrum of the former at its next return; than, in itself a consummation long most earnestly wished for, but now more than ever to be desired, to test the penetrating theory of a Russian Astronomer and Mathematician.

Iridescent Clouds

ON pp. 148 and 149 of the current volume of NATURE there are two letters describing "iridescent clouds," and the idea is conveyed that this phenomenon is only of late occurrence. That this is hardly justifiable, the following account from a diary will show:—

At Knoxville, Tennessee, on the afternoon of February 16, 1878, after many days of cloud and drizzle—something unusual in that country—the sun being about 10° high and the sky partially covered with large haze-clouds, there was noticed in the south-west, against one of these clouds, a slightly curved band of prismatic colours about 90° in length; which, but for its position in the west, might have been mistaken for a rainbow—concave toward the sun, the sun, however, not at the centre of curvature, and about 30° distant from it. The green was most strongly marked; this shaded off on each side, and on the side of the band next the sun was red; upon the opposite side the colour was less distinct, but there it seemed to be reddish.

Again, during September or October 1882 (this from memory), at the same place, about sunset, with a patched, cloudy sky, the sun not visible, the prismatic colours were noticed in the south-west near a break in the clouds. This time the colours were in the form of an elongated ellipse, with indistinct edges, between 2° and 3° in greatest length.

Then, during the fall of 1883, the prismatic colours were once noticed under similar circumstances to those mentioned here in Virginia.

W. G. BROWN

University of Virginia, Virginia, U.S.A., January 13

The Iridescent Clouds alluded to above

In our northern as well as insular position, with weakened sunshine and an atmosphere always more or less darkened by coal-smoke, we must be prepared to allow much for what is, and is to be, seen of the grander meteors of meteorology in the more southern latitude, clearer air, and intensified climate of the Virginian portion of so great a continent as America. But before any one there can claim to see frequently that very phenomenon of the iridescent clouds, communicated last December to NATURE by various persons, but by myself perhaps as the chief culprit, he must be quite sure, amid the crowd of known and already described parhelia, mock suns, broken rainbows, &c., that what he sees has the same discriminating optical characteristics as those particular clouds now in question; and that any one of his cases was, in America, so unusually brilliant a display of them, and so widespread an instance of it, that from one end of the States to the other it was on the same day similarly seen, wondered at, and declared even by gray-headed old men to be new to them, in at least anything approaching that astonishing degree of splendour and perfection, though by no means new to creation over a longer lapse of time.

The Virginian letter-writer, however, speaks merely of what he himself saw, describes the colours as prismatic, in place of the anti prismatic arrangement witnessed here, and alludes to one case of a curved band "about 90° in length," which contrasts exceedingly with the forms and sizes noted in this country.

In fact I can hardly give a stronger confirmation of the rarity, and both the general character and universality of the phenomenon on that occasion, for all parts of Great Britain than by concluding with the following extract from a letter by Prof. A. S. Herschel of Newcastle-on-Tyne, dated December 25 :—

"I saw," he writes "(and photographed from a window, but lost by over-exposing the plate, unfortunately), the iridescent clouds of Thursday's sunset you describe in NATURE, and could, as you wrote, be possibly *imagined!* They were seen also in the south of England (Kent) between 2 and 3 o'clock on the same afternoon.

"Mr. *N.* here says, in resumption of what they were probably, that he often sees such coloured fringes and colour-bows, in circles too, on clouds near and round the sun, by looking at the sun's reflection and that of the clouds just round him, in the plate-glass window of his drawing-room.

"So no doubt it was a good instance only of a common sight, but an instance yet, I should say, not to be seen much oftener than once or twice in a century!"

To that opinion I do not presume to add one word.

Manx Cats

WITH reference to Mr. Francis Galton's remarks in NATURE on Manx cats, I should like to ask whether any of your readers can assist me. Some little time ago I imported a few Manx cats with a view of trying experiments with them in crossing. But, as Mr. Galton says, it is difficult to get cats to breed in confinement, and of course it is of no use for the purpose of my experiment to allow the animals to roam at large among ordinary cats. Acting upon Mr. Galton's suggestion, therefore, I write to ask whether any of your readers happen to know of any island within a reasonable distance from town where a breed of Manx cats could be established. It is not necessary that the island should be a marine one. Any piece of ground insulated by fresh water would do equally well, provided it were of moderate size and not already tenanted by cats. If any of your readers should know of such a place I should be greatly obliged to them for a reference to its locality.

I may take this opportunity of further inquiring whether any of your readers would care to lend me, or tell me where to procure, a really good talking parrot for the purposes of systematic observation.

GEORGE J. ROMANES

Cross-breeding Potatoes

IT is well that your correspondent, Mr. James Melvin, has called attention to the dubious and erroneous ideas which now largely prevail on this subject. There is no reason to suppose that hybrids arising from *Solanum Maglia* will be disease-proof, for *S. Maglia*, like *S. tuberosum*, is one of the known hosts of the potato fungus, *Peronospora infestans*.

The errors at least to have arisen from the unfortunate conclusions,—"Economic Suggestions," given by Mr. J. G. Baker in his otherwise admirable paper laid before the Linnean Society, April 1884, p. 505.

Mr. Baker thinks that, because *S. Maglia* comes from humid positions in America, it will succeed in Britain better than *S. tuberosum*, a plant of the dry hills. The correctness of this idea I should very much question, the great strongholds of fungi being humid places. The fact of the habitat is an important one, but the deduction made from it is questionable.

Mr. Baker says the potato plant in its present tuber-bearing state is in a "disorganised and unhealthy condition." This view also is very much open to question: there is no evidence of disorganisation and unhealthiness in cultivated potatoes. Cultivated potato plants are no more disorganised and unhealthy than are any of our other cultivated kitchen garden plants, fruits, flowers, or domestic animals, including man himself. The notion that disorganised and unhealthy plants are "fitting subjects for the attacks of fungi and aphides" is a mistake, for fungi (*i.e.* parasitic fungi,—the fungi Mr. Baker has in view) do not grow upon "disorganised and unhealthy plants;" they require healthy plants on which to grow. Of course vegetable parasites require for their sustenance the vigorous elaborated juices of healthy plants, not the vitiated juices of "disorganised and unhealthy" ones.

Leaving theory for fact, I may point out that in the published results of experiments made by Dr. Hogg last autumn, both *S. Maglia* and *S. Jamesii* were badly diseased with parasitic fungi, and in Mr. Thomas Laxton's published experiments nearly the whole of the plants of *S. Maglia* and *S. Commersoni* (the two species specially recommended by Mr. Baker), as well as *S. Jamesii*, "disappeared from disease."

A year or two ago Mr. John King, British Vice-Consul, Carrizal, Bajo, Chili, sent to this country twenty stones of potatoes from positions in Chili where, during an experience of more than twenty years, the disease of potatoes had never been seen. It was perfectly unknown to the growers there.

These twenty stones of potatoes were planted in different parts of Great Britain and were a failure. They fell before *Peronospora infestans* quite as readily as did our own common potatoes.

No doubt good will arise from the experiments now being carried out, but not in the way generally assumed. The only theme for regret is the publication at the outset of (as I think) curiously mistaken deductions. These deductions, coming from such an excellent botanist as Mr. Baker, have led potato growers very much astray.

WORTHINGTON G. SMITH

Earthquake

THE annexed copy extracts from letter dated Kingston, Jamaica, January 8, from Capt. Spray, of our s.s. *Marson*, will no doubt interest you. Are we right in thinking that the shock he felt was probably connected with the Spanish earthquakes?

J. G. S. ANDERSON

5, Fenchurch Avenue, London, E.C., January 27

Extract of Letter from Capt. Spray

Kingston, January 8

On the morning of December 22, 1884, in lat. 36° 48′, long. 19° 25′ W., we felt a shock as if the ship was grinding over a reef, although there was no difference in speed of engines; stopped and made every examination, but found no cause. My opinion it was a shock of earthquake, as some years before, nearly in the same place, I felt one more severe than the last.

An Instance of "Protective Resemblance"

IN Mr. Johnston's interesting account of the ascent of Mount Kilimanjaro, in Equatorial Africa, which appears from time to time in the *Daily Telegraph*, occurs a passage which seems deserving of being rescued from the comparative oblivion of the pages of a daily newspaper. It will be found in the number of the 16th inst., and is as follows:—"Other noticeable features in the scene were the tall red ant-hills and, strange imitation, the tall red antelopes, a species of hartebeest, resembling faintly in shape the form of a giraffe with sloping hind-quarters, high shoulders, and long neck. Being a deep red-brown in colour, and standing one by one stock-still at the approach of the caravan, they deceived even the sharp eyes of my men, and again and again a hartebeest would start up at twenty yards distance and gallop off, while I was patiently stalking an ant-hill, and crawling on my stomach through thorns and aloes, only to find the supposed antelope an irregular mass of red clay."

New University Club, January 20 J. C. G.

Hibernation

WILL you allow me to invite attention of anthropologists and zoologists to the very remarkable (and to me surprising) statement contained in the article "Hibernation" (W. F. Kirby), last edition of the "Encyclopædia Britannica." Reference is there made to a work by Mr. Baird, entitled "Human Hybernation" (1850), giving examples on "unimpeachable authority" of the powers of religious ascetics in India of throwing themselves into a state closely resembling hibernation for an indefinite period; and quoting a case of a Fakir who was actually buried alive at Lahore in 1837 in presence of Runjeet Sing and Sir Charles Wade, and was dug up and restored to consciousness several months afterwards! Now, it is ascertained that hares can exist for weeks together buried in the snow, and if this power of hibernation can be developed at will, might it not also be so on necessity, and explain the former existence of the Siberian mammoth, through the winter months: these animals might, as winter approached, have withdrawn to sheltered hollows, where

they were eventually snowed up and covered with snow. This possibility may have before been started, but seems to me to be reasonable and probable. K. BUSK

Athenæum, February 2

Our Future Clocks and Watches

IF clocks are to strike at all, surely once per hour is insufficient, while four times is excessive; the high hour-numbers even now are inconvenient to count, and with the quarters heard alone it is possible to make a mistake of an hour. I cannot but think, then, on the whole, that the necessities of ship-life have long driven mariners into the very best method, free from all difficulties, and that, whatever our way of noting hours, we could do no better than adopt the naval half-hour strikings for land-clocks, recommencing with each four-hour watch. Some confusion with the existing ways, as long as they survive, is inevitable, and equal whatever change is made.

A mistake of four hours is just as unlikely as one of twelve. We should probably soon find names for the different four-hour divisions; for example, we might denote each half-hour by some letter or cypher. EDWARD L. GARBETT

THE LIFE-HISTORY OF THE LYCOPODIACEÆ

THE area within which really notable discoveries are possible—at any rate amongst the higher plants—in the field of vegetable morphology is becoming very circumscribed. For some time the complete life-history of the *Lycopodiaceæ* has been a missing chapter in our text-books. Hofmeister, like others, had unsuccessfully sown the spores, and he could only speculate as to the probability of their producing—if the proper conditions could be known—a prothallium like ferns. And Spring, the monographer of the group, had hazarded the extraordinary theory that the existing representatives of the group were only represented by male plants, the females having been lost in some remote geological catastrophe.

De Bary made in this, as in so many other fields, the first real advance. He described in 1858 the early stages of the germination of the spores of *Lycopodium inundatum*. But just as Hofmeister had failed to get the spores to germinate at all, so De Bary failed to get the development of the prothallium to advance beyond a very early stage. Thus matters stood till 1872, when Fankhauser had the good fortune to find, in a botanical excursion, young plants of *Lycopodium annotinum*, still united to their parent prothallium.

For my own part, I have always felt that it might be the chance of any wide-awake observer to turn the next unread page in this curiously reserved history. And I have never failed to remind the younger botanists who have consulted me as to a promising direction for work that this was a possibility they should never lose sight of. Within the last few days, however, two fresh contributions to the subject have come into my hands.

The first number of the *Botanisches Centralblatt* for this year contains a paper by Bruchmann, who has, if I mistake not, already done some good work in the vegetative morphology of Lycopodium. He has had the good luck to repeat Fankhauser's happy find, and to have come across, at the end of August last, living prothallia of the same species.

But the paper [1] which will mark its epoch in the history of Lycopodium is that for a separate copy of which I am indebted to my friend, Dr. Treub, the accomplished director of the renowned Botanic Garden at Buitenzorg in Java. Six years ago, when he had no thought that he would ever be able to prosecute botanical research in the tropics, he also made, as so many others have done, unsuccessful attempts to obtain the development of Lycopodium spores. On his arrival at Buitenzorg, he lost no time in endeavouring to find the prothallia of tropical species. He seems to have all but succeeded in discovering those of *Lycopodium cernuum*—but for an accidental circumstance which threw him off the scent—in the first year of his residence there. Subsequently, he sowed the spores on the trunks of trees, and after a delay which led him to abandon any hope of success, he obtained satisfactory results from one of the sowings. Now he is acquainted with the prothallia of three species of Lycopodium, and hopes to be able to describe even a fourth.

In the present paper, which is illustrated with nine admirable plates, Dr. Treub gives an exhaustive account of the prothallium of *Lycopodium cernuum*. It is curious to observe, however, that in artificial cultures he did not succeed in carrying the development further than De Bary had done some time ago with *L. inundatum*. Fortunately, prothallia which he discovered under spontaneous conditions of development exactly fitted in where the others stopped.

The adult prothallium is a very singular structure, consisting of a sort of short cylindrical axis, half immersed in the soil at one end, where it is furnished with root-hairs. The upper extremity bears a tuft of small leaf-like lobes. The archegonia and antheridia are found on the upper part of the cylindrical axis, forming a kind of ring or crown near the tuft of lobes. The prothallium therefore presents a type morphologically more differentiated than is met with elsewhere amongst the vascular cryptogams. While this is the case with the sexual generation (oophore), the spore-bearing generation (sporophore) in its embryonic stage is less differentiated than is the case, for example, in the fern. The embryonic root is suppressed, and the whole embryo, which is wholly parenchymatous, approximates in its morphological characters to those of the prothallium.

JOHN GWYN JEFFREYS

IT is with much regret we have to announce the death of this veteran conchologist. Dr. Gwyn Jeffreys, who was in his usual health the day before, and in the evening attended at the lecture given by his son-in-law, Prof. Moseley, at the Royal Institution, was seized on Saturday morning, January 24, with a fit of apoplexy, and at five o'clock on the same afternoon passed peacefully away. He was the last, or almost the last, of a band of marine zoologists of a former generation who had been his friends. Dilwyn, Cocks, and Couch; Fleming, Gray, Forbes, Alder, and Albany Hancock; Johnston and William Thompson; Barlee and Waller are names of the past.

Dr. Gwyn Jeffreys was born at Swansea on January 18, 1809, and had thus just completed his seventy-sixth year. While a boy he showed a taste for natural history, collecting the insects and shells of South Wales. When only nineteen he contributed a paper to the Linnean Transactions, "*A Synopsis of the Pneumonobranchous Mollusca of Great Britain*," and from that date until the present time he has been adding by his writings to our knowledge of the molluscan fauna of Europe and the North Atlantic. His most important works are: "*British Conchology*," in five volumes, and a series of papers (unfortunately unfinished) in the Proceedings of the Zoological Society, on "*The Mollusca of the 'Lightning' and 'Porcupine' Expeditions*, 1868-70." At the age of twenty he was elected a F.L.S., and in 1840 F.R.S., and he was an honorary LL.D. of St. Andrews. He was one of the most regular members of the Royal Society Club, and took great interest in the meetings of the British Association, which he almost always attended, taking a more active part in 1848, when Local Treasurer at the first meeting at Swansea, in 1880, when a Vice-President at the last meeting held in the same town, and in 1877, when President of the Biological Section. For many

years he was Treasurer of the Linnean, and also of the Geological, Society.

Dr. Gwyn Jeffreys's profession was the law. He practised as a solicitor at Swansea until 1856, in which year he was called to the bar, but soon afterwards altogether retired from business. He then left London, and went to reside at a fine old house, Ware Priory, which he had purchased in Hertfordshire. Here it was his delight to hospitably entertain his scientific friends and any foreign naturalists of kindred tastes to his own who might be visiting London.

He may be considered perhaps as the father of dredging in our seas. When practising as a solicitor he was diligent in his profession, and could only spare himself short holidays; yet as early as 1841 he paid his first visit to Shetland. Through a number of years, when unable to give much time himself to collecting, he joined Mr. Barlee in partnership, and while his friend gave his whole time to dredging and collecting, Jeffreys shared the expense and the mollusca.

Shortly after Barlee's death Jeffreys was enabled to devote himself more exclusively to scientific work, and from this time commenced an important series of dredging operations which continued to the last. His friends were now the late Mr. Waller and the Rev. A. M. Norman, and in company with these naturalists explorations were made of the most important parts of the British coasts. A yacht, the *Osprey*, at first lent by Dr. Gwyn Jeffreys's brother-in-law, Mr. Nevill, but subsequently purchased by him, was employed in these investigations. The summers of 1861, 1862, 1863, 1864, 1867, and 1868 were spent in dredging, down to 170 fathoms, the sea around the Shetland Islands; in 1865 Guernsey and Jersey were visited; in 1866 the Minch; and in 1870 the deep water off Valentia on the south-west of Ireland.

Private enterprise now gave way to Government expeditions. In 1869 H.M.S. *Porcupine* was sent to explore that portion of the Atlantic which lies off our western shores, and Dr. Gwyn Jeffreys had charge of the scientific work of the first cruise off the west of Ireland. In the succeeding year (1870) the same vessel was sent to investigate the great depths off the southern coasts of Europe, and Jeffreys was the naturalist on board during the first cruise, which was off the Spanish and Portuguese coasts. In 1876 he went in H.M.S. *Valorous*, which accompanied the last Arctic Expedition as far as Baffin's Bay, when very successful dredging was carried on in Davis Strait and the North Atlantic Ocean during the homeward voyage. In 1880 he and his friend, Dr. Norman, by invitation of the French Government, took part, with a staff of naturalists of that country, in dredgings in great depths off the Bay of Biscay in *Le Travailleur*. In 1878 and 1879 Drs. Gwyn Jeffreys and Norman went together to Norway and dredged Oster Fiord to the north of Bergen, the Hardanger Fiord, and at Drobak on the Christiania Fiord.

Besides all this direct scientific collecting Dr. Jeffreys for many years has been in the habit of taking a tour on the Continent for the purpose of carefully examining all leading and typical collections of European mollusca, and more especially the products of the various deep-sea expeditions of other nations.

He married a daughter of the late R. J. Nevill, Esq., of Llangennech Park, Carmarthenshire, a talented and accomplished woman who predeceased him, and has left six children.

Dr. Gwyn Jeffreys was J.P. for the counties of Glamorganshire, Breconshire, and Hertfordshire, and for the last county was also a D.L., and served as High Sheriff in 1877.

It cannot but be a matter of deep regret to all British naturalists that Dr. Gwyn Jeffreys's magnificent and unequalled collection of European mollusca, amassed with so much labour and toil and expense, rich to overflowing with types not only of species described by himself, but by almost every author, should go out of this country. Two years ago it was purchased by the American Government. We congratulate our Transatlantic cousins on having it, but it would have been of far greater value in Europe.

ALEXANDER MURRAY, C.M.G.

BY the death of Mr. Alexander Murray, Canadian geology has lost one of its veteran pioneers. This estimable man belonged to a good Perthshire family, and was born at his father's estate of Dollerie in 1811. He went into the navy at the age of fourteen, served in the Mediterranean and was present at the battle of Navarino, was subsequently employed in the West Indies, Halifax, and other stations, and finally quitted the service in 1837. There being no prospect of his advancement in the pursuit of war, he turned his attention to the arts of peace, went to Canada, and bought land there with the view of settling as a farmer. During the rebellion which broke out soon after his emigration he had once more an opportunity of seeing active service. But he had not yet found the proper field for the exercise of his powers. His attempts at farming failed, and his prospects were rather blank, when at last he made the acquaintance of Mr. W. E. Logan, then starting the Geological Survey of Canada. He had had no training in science of any kind, but the mode of life offered by the Survey seemed just what he longed for, and he gladly accepted the proposal that he should join the staff. Before actually beginning his new duties he resolved to do what he could to qualify himself for them. He returned to this country, studied geology theoretically at Edinburgh, and afterwards practically in Wales. In 1843 he went back to Canada and at once began work, remaining at his post for twenty years. He was one of the first and ablest of the stratigraphers with whom Logan traced out the general geological structure of the Dominion. His explorations extended over most of the settled parts and over a large area of forest-land in Western Canada, where he laid down the main lines of structure and the areas of distribution of the rocks. He likewise examined parts of Gaspé and other tracts in the eastern portion of the Dominion. But his most important labours were devoted to the investigation of Newfoundland, of the Geological Survey of which he had charge from 1863 to 1885. From 1866 onwards he prepared an Annual Report of the progress of his work in that colony. These Reports collected by him, and republished as a volume in 1881, contain a summary of all that is known regarding the geological structure of Newfoundland, and will remain as a lasting monument of Mr. Murray's skill as a stratigraphical geologist, and of the courage, patience, and tact with which he overcame all physical and political difficulties. One of his last labours was the completion and publication of a geological map of the whole of Newfoundland—a work at once beautiful in execution and of the first importance in regard to the industrial growth of the colony. Very few of our colonies yet possess complete geological maps, and hardly ever are they so largely the work of one man as this one. Newfoundland has never adequately recognised how much it stands indebted to Mr. Murray for his share in laying the foundation on which its future development must rest.

SEARLES V. WOOD

AMONG the recent losses which have befallen the geologists of this country not the least is the death of Mr. Searles V. Wood. Himself the son of a geologist, he began his scientific work early in life. He may be said to have been educated upon Tertiary geology, and though at first disposed to wander into wider fields of

i and speculation, it was in tracing the history of nger formations that he did his best work and ie chief part of his scientific career. Since the 64 he has been unweariedly engaged in investi- the history of the Pliocene and Post-pliocene of the East of England. Taking up this subject nction with Mr. Harman, he soon became con- hat no satisfactory progress could be made in it deposits in question had been actually mapped detail. Accordingly the two observers began to em on the one-inch Ordnance Map, Mr. Wood he southern half of the area, including Essex and the whole of Suffolk. This survey, which for ess and accuracy has seldom been equalled by of any private workers, remains unpublished, a reduction of it, on the scale of four miles to an s issued in 1872. Mr. Wood eventually gave up iness, which was that of a solicitor, in order to imself with more uninterrupted zeal to the prose- of his favourite science. The bodily feebleness ebarred him from much active work out of doors only to quicken his energy for literary labours. f the best fruits of his life-long devotion were d into his two long memoirs on "The Newer Period in England," published in 1880 and 1882 Geological Society. But his friends anticipated eful work still to come from one who had pursued ies with such intelligence and zeal, and who had ched his prime. In his death, at the age of fifty- y mourn one who was ever ready cheerfully and to impart to others the knowledge he possessed who never hesitated to admit an error when he ed it, and who leaves behind him a notable of quiet fortitude and enthusiasm.

A SUNSHINE RECORDER

ine 28 of last year I had the honour of bringing fore the Physical Society a preliminary notice of nshine recorder,[1] and as we have now had more months' experience of its working, it is possible ie of your readers might be interested in hearing sults obtained.

pparatus is of simple construction. It consists ass sphere silvered inside and placed before of a camera, the axis of the instrument being parallel to the polar axis of the earth. The rangement will be readily understood by an in- of Fig. 1. The light from the sun is reflected globe, and some of it, passing through the lens, image on a piece of prepared paper within the

In consequence of the rotation of the earth, the escribes an arc of a circle on the paper, and when is obscured, this arc is necessarily discontinuous. age is not a point, but a line, and in certain positions of the sphere, lens, and paper, the line and very thin, so that the obscuration of the sun one minute is indicated by a weakening of the

e actual apparatus the sphere is an ordinary ottomed flask about 95 mm. in diameter, and the imple double convex lens of about 90 mm. focal The sensitive paper employed is the ordinary ssiate paper now so much used by engineers for tracings. This was selected in consequence of with which the impression is fixed, for the paper equires to be washed in a stream of water for six no chemicals being necessary. When the paper adial lines containing between them angles of 15° en from the centre of the circular impression, give the hour scale, the time of apparent noon course given by a line passing through the plane eridian. Fig. 2 is a copy of the record of June

[1] *Proc. Phys. Soc.*, vi. 216; *Phil. Mag.*, August 1884, p. 141.

27, 1884; in the morning the sun shone brightly, towards noon clouds began to form, and in the afternoon the sky was hazy. The field in which the instrument is placed is

FIG. 1.

surrounded by trees, so the ends of the trace are cut off sharply by shadows.

With the alteration of declination of the sun, the light

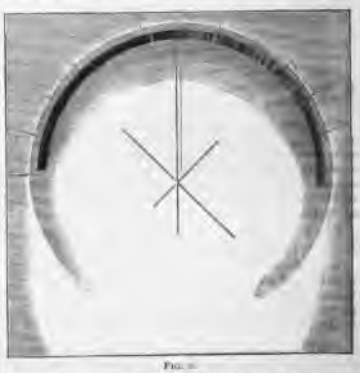

FIG. 2.

entering the camera is reflected from different portions of the sphere, and an alteration of the position of the focus results. This may be corrected in three ways: by moving

(1) the paper, (2) the lens, or (3) the sphere. In the present apparatus the first method has been adopted, and now the camera is about twice as long as it was in June. As a consequence the circular image is enlarged, and the light therefore weakened, and that at a time of year when it can least be spared. If the focus is altered by moving the lens, the winter circle is small and the summer circle is much larger. This would perhaps be too much to the advantage of the winter sun. If, however, the lens and paper are maintained at a constant distance, and the sphere alone moved, the circles are more nearly of the same diameter throughout the year, the winter one still remaining the smallest. This seems, therefore, to be the most advantageous arrangement, and the one that will be adopted in future. It may be possible also to find positions for the sphere, lens, and paper such that the intensity of the image is a true measure of the intensity of the sun's light; at present, however, this has not been done, the want of sunlight and the press of official work having prevented the carrying out of the necessary experiments. A more sensitive paper might also be used with advantage, and in observatories where photographic processes are carried on daily there would be no difficulty on this score, but my principal object was to devise some economical instrument requiring only easy manipulation, so that at a considerable number of places the instruments might be set up, giving a more useful average of the duration of sunshine than can be obtained from only a few stations. The instrument also gives a record when the sun is shining through light clouds; in this case the image is somewhat blurred and naturally weakened, and it may be difficult or impossible to employ any scale for measuring the intensity under such conditions, but it must be remembered that, even when the sun is shining in this imperfect manner, it is really doing work on the vegetation of the earth, and deserves to be recorded.

It may be well to say that the instrument is in no way protected. Some friends, whose opinion I highly value, urged me to patent it; but as I strongly hold the view that the work of all students of science should be given freely to the world, the apparatus was described at the Physical Society a few hours after the advice was given, lest the greed of filthy lucre should, on further deliberation, cause me to act contrary to my principles.

Cooper's Hill, January 20 HERBERT MCLEOD

NOTES

PROF. PRESTWICH has been elected a Corresponding Member of the Paris Academy of Sciences in the place of the late Italian geologist, Quintino Sella.

SIR WILLIAM THOMSON opened the laboratories at University College, Bangor, on Monday, with an address, in which he referred to the spread of the laboratory system and the good results which thereby had accrued to science and scientific education. We hope in an early number to give a detailed report of Sir William Thomson's address, with a description and plan of the laboratories.

THE honorary degree of LL.D. has been conferred upon Prof. Ray Lankester by the University of St. Andrew's.

WE understand that Dr. Dallinger, F.R.S., will take the opportunity of his presidential address to the Royal Microscopical Society to give an account of a new septic organism. The address, which will be fully illustrated, will be delivered on Wednesday next at 8 p.m.

THE Paris Academy of Sciences has decided to send a mission to explore the districts in the south of Spain where the recent earthquakes took place. M. Fouqué, Professor of Geology in the College de France, is appointed chief of the mission, which was to leave Paris last week. The other members are M. Lévy, mining engineer and sub-director of the geological laboratory of the College of France; M. Bertrand, mining engineer; M. Barrois, of the Faculty of Sciences at Lille; and MM. Rittiez and Oppret, of the College of France.

AMONGST the honorary members elected to the Italian Society of Geography at its meeting of the 25th ultimo was Mr. Joseph Thomson.

A MEETING of much interest was held at the Rooms of the Asiatic Society on Monday in connection with the establishment of a British School of Archæology at Athens. Already Germany, France, and the United States have been in the field for some time; but though the Greek Government has presented to the English Society a choice site of considerable extent for a school, funds are lacking wherewith to erect the building and carry on the work. We need not insist on the value of archæology in historical research,—all the speakers on Monday were agreed as to that; for a scientific knowledge of the past, it bears the same relation to academical study as the researches carried on by the Naples station do to the home study of biology. At present only 4000*l.* are in the hands of the Committee, but four or five times that amount is required ere the School can start with any hope of efficient work. There are several learned societies with ample means, interested in the varied work which would be carried on by such an institution, and to these, and to individuals who have money to spare and wish to put it to good use, we commend the scheme. The treasurer is Mr. Walter Leaf, Old Change, E.C.

WE regret to learn of the death of M. Dupuy de Lôme at the age of sixty-eight years. M. de Lôme was well known as a naval engineer, and his name is intimately associated with modern ballooning.

THE Council of the Royal Meteorological Society have arranged to hold, at 25, Great George Street, S.W. (by permission of the President and Council of the Institution of Civil Engineers), on the evenings of March 18 and 19 next, an Exhibition of Sunshine Recorders and Solar and Terrestrial Radiation Instruments. The Exhibition Committee invite the co-operation of those interested, as they are anxious to obtain as large a collection as possible of such instruments. The Committee will also be glad to show any new meteorological apparatus invented or first constructed since last March; as well as photographs and drawings possessing meteorological interest.

IN his inaugural address as Lord Rector at St. Andrew's last week, Lord Reay stated very forcibly his ideas of what a university should be at the present day, encouraging every form of culture and research. Referring to science, Lord Reay asked: "Are we to have a separate Faculty of Science? I should say certainly. Just look at the field covered by a Faculty of Science. It is preparatory for medical science, and our engineers, our manufacturers, our analysts, our botanists, our zoologists, our astronomers, our naval constructors, our geologists, our biologists, our physiologists, our mineralogists, our agriculturists, should obtain scientific degrees. I do not see why a faculty having such an immense area should remain linked with another which has quite different objects to pursue. The same work done by the French Ecole Polytechnique I wish to see done at the universities; and if the Germans have lately spent 340,000*l.* on a new college for technical education at Berlin, I should like to ask what possible reason can be adduced for stinting science-teaching in Scotland at a moment when the report on technical instruction has pointed out that 'theoretical knowledge and scientific training are of pre-eminent importance, as in the case of the manufacturer of fine chemicals, or in that of the metallurgical chemist, or the electrical engineer, and that to these the higher technical instruction may with advantage be extended to the age of twenty and twenty-two.' Here, then, is a clear case even for a

ıe ts grant Government aid. With reference to the science I should like to make a remark which applies also to the culties, but very specially to this faculty. I should wish it considerable power to establish lectureships on any subject for which a specially gifted man should be found. the number of his pupils might be very limited, the ion of the results of his research, carried on at the Uni- would raise it in what I should like to call the inter- scale. Besides, the knowledge of such prizes being le would stimulate original research among the most undergraduates. I wish those lecturers to be incur- in the University."

ave received the Report of the Board of Managers of ollege Observatory for 1883-84. Dr. Elkin is doing good ith the heliometer. The principal lines of investigation h attention has been directed are as follows:—"(1) The ation of the Pleiades. The interest attaching to this ll lie both in the new and independent determination of ative positions of the stars of this important zodiacal nd in the comparison with the similar determination ith the Königsberg heliometer nearly half a century ago, as with the later Paris results. The plan adopted will it is hoped, trustworthy tests of the reliability of the ent both for absolute and relative distances and angles of From February 24, the date of the arrival of the g eye-pieces from Messrs. Repsold, to April 12, after he stars are lost in the sun's rays, about one-third of the d plan has been accomplished. As the group will come ourable position for observation during the last four of the year, there is, therefore, all reasonable hope to ıe work during that time. (2) A considerable amount of s been devoted to the determination of places of the lative to stars within measuring-reach of the heliometer. ncipal object in view is the determination of the paral- equality in the moon's motion, the deduction of which eridian and other observations is, as is well known, with some difficulty. (3) Advantage has been taken of urable opportunity afforded by the approaching inferior ion of Venus for a series of observations on the r of this planet, of which a number have been already

RCULAR from Mr. H. H. Warner, of the Rochester Astronomical Society, gives the following information as Warner Astronomical Prizes:—First. Two hundred dol- nach and every discovery of a new comet made from r 1, 1885, to February 1, 1886, subject to the following ns:—(1) It must be discovered in the United States, Mexico, West Indies, South America, Great Britain, Australian Continent and Islands, either by the naked lescope, and it must be unexpected, except as to the f 1815, which is expected to reappear this year or next. discoverer must send a prepaid telegram immediately to wis Swift, Director Warner Observatory, Rochester giving the time of the discovery, the position and direc- motion, with sufficient exactness, if possible, to enable ne other observer to find it. (3) This intelligence must *mmunicated to any other party or parties*, either by letter, , or otherwise, until such time as a telegraphic acknow- has *been* received by the discover from Dr. Swift, re should be observed regarding this condition, as it is to the proper transmission of the discovery, with the the discoverer, to the various parts of the world, which mediately made by Dr. Swift. Discoverers in Great the Australian Continent and Islands, West Indies, h America are absolved from the restrictions in con- 1) and (3). Second. Mr. Warner will also give a prize of 200 dols. in gold to any person in the world who will write the best 3000-word paper on the cause of the atmospheric effects ("red light," &c.) accompanying sunset and sunrise during the past sixteen months. It is desired that these papers be as original as possible, both in facts, observations, and treatment. Essays must be exclusively sent prepaid to Dr. Lewis Swift, Director Warner Observatory, Rochester, New York, must be written in English, on one side of the paper only, with ink, and must be in the simplest untechnical phrase.

WE learn from *Science* that Mr. Henry Lomb, of Rochester, New York, has offered, through the American Public Health Association, the sum of 2800 dols., to be awarded as first and second prizes for papers on the following subjects:—(1) Healthy homes and foods for the working classes: first prize, 500 dols.; second prize, 200 dols. Essays to be of a practical character, devoid, as far as possible, of scientific terms. They must be within the scope and understanding of all classes, and designed especially for a popular work. (2) The sanitary conditions and necessities of schoolhouses and school-life: first prize, 500 dols.; second prize, 200 dols. (3) Disinfection and individual prophylaxis against infectious diseases: first prize, 500 dols.; second prize, 200 dols. (4) The preventable causes of disease, injury, and death, in American manufactories and workshops, and the best means and appliances for preventing and avoiding them: first prize, 500 dols.; second prize, 200 dols. All essays written for the above prizes must be in the hands of the secretary, Dr. Irving A. Watson, Concord, N.H., on or before October 15, 1885. It is expected that arrangements can be made to have these essays widely distributed to the public, and to the persons mostly interested in the respective subjects in the United States. The American Public Health Association earnestly appeals to those able to compete, to take part in this work, which, it is believed, will do much to augment the health, comfort, and happiness of the people.

WE are glad to notice that classes for the instruction and study of elementary astronomy have been established by the Liverpool Astronomical Society, and will meet every Tuesday in the Association Hall, Mount Pleasant. The opening meeting of the class was held on Wednesday, January 21, at—we are informed—twenty o'clock (eight p.m.), when Mr. Isaac Roberts, F.R.A.S., F.G.S., presided and addressed the students. The class throughout the course will be conducted by Mr. James Gill, of the Liverpool School of Navigation.

THE distinction of Associate of the Linnean Society has recently been conferred on Mr. James E. Bagnall, of Birmingham. Mr. Bagnall is one of the Vice-Presidents of the Birmingham Natural History and Microscopical Society, of which he has for something like a quarter of a century been one of the most useful and hard-working members. He has devoted his principal attention to the study of botany—structural and systematic. His most important published work is the latest and by far the best "Flora of Warwickshire," which has appeared by instalments extending over several years in the *Midland Naturalist*. This work will, we are informed, shortly appear in a thoroughly revised form as an independent publication. Mr. Bagnall belongs to the class of naturalists of which Thomas Edwards is the type.

AT the last meeting of the China Asiatic Society at Shanghai an instrument, which was a species of primitive telephone, was presented for inspection by Dr. Macgowan of Wenchow. It consisted of two bamboo cylinders, from 1½ to 2 inches in diameter, and 4 inches in length; one end of each was closed by a tympanum of pig-bladder, which was perforated for the transmitting string, the latter being kept in place by being knotted. This rude instrument is called the "listening tubes," and is employed for amusement as a toy, conveying whispers

40 or 50 feet. It is unknown in many parts of China, the provinces of Che-kiang and Kiangsu being the only ones, so far as can be ascertained, where the listening tubes are employed. Besides this toy, Chinese ingenuity produced, about a century and a half ago, the "thousand mile speaker." This implement is described as "a roll of copper, likened to a pipe, containing an artful device; whispered into, and immediately closed, the confined message, however long, may be conveyed to any distance, and thus, in a battle, recent instructions may be conveniently communicated. It is a contrivance of extraordinary merit." The inventor of the "thousand-mile speaker," one Chiang Shun-hsin, of Huichou, flourished during the reign of Kang-hsi, during parts of the seventeenth and eighteenth centuries. He wrote on occult science, astronomy and foreign physics, and the above description of his invention was copied from his works into a provincial encyclopædia. At the time the latter work was published—in the reign of Kien Long—there was no longer an instrument of this kind in the province, as the ingenious invention appears to have perished with the student who contrived it.

THE following very interesting table has been compiled from the records of the meteorological observatory at Tokio. It gives the total number of recorded earthquakes which occurred in the respective months during the ten years ending December 10, 1884:—

January	53	July	36
February	50	August	27
March	73	September	15
April	43	October	47
May	51	November	51
June	40	December	60

The list would, of course, need to be in full detail for each month of each year, in order that any safe deduction might be made from it; but the general notion that there are more earthquakes in winter than in summer receives some support from this table. The average per month for the ten years is 45; that for the six winter months (October-March) is 56; and for the six summer months 35, or about 40 per cent. less. An important element of disturbance in the figures would be the great improvement in seismological instruments since 1874, and the consequent registration of movements which would previously have passed unnoticed.

THERE have been a number of earthquake shocks during the past week. Another severe shock, accompanied by what is described as a tremendous report, occurred at Alhama, on January 27. By the fall of a house one person was killed and two others were injured. On the 27th and 28th fresh shocks occurred in the hot spring district of Southern Styria; also at four o'clock on the morning of the 27th a severe and prolonged shock was felt at Valparaiso. On the 31st a shock occurred at Algiers, destroying eight Arab houses. The shock was also felt at Setif.

MR. JAMES JACKSON, of the Paris Geographical Society, has issued a new and much extended list of various speeds in metres per second. It begins with the Mer de Glace at 0·0000099 m. per second, and concludes with the current from a Leyden jar in a copper wire of 0·0017 m. at 443,500,000 m. per second.

WE are glad to see that the *Health Journal*, the first number of which we noticed, is still continuing to do good work in connection with sanitary science. We have before us the twenty-first number, which contains several useful articles. We commend the *Journal* to the notice of those interested in the subject. It is published by Heywood, of Manchester.

THE *Journal de Saint-Pétersbourg* states that the first Russian school for Mussulmans has been opened at Tashkend. The pupils, who belonged to the families of native notables, numbered forty-one at the commencement. It is proposed to open schools of the same kind elsewhere.

WHEN M. Barral died he had written the larger part of a "Dictionnaire d'Agriculture." The first number, which contains 250 pages large 8vo, two columns, closely printed, has just been published by Hachette and Co. About twelve similar parts will follow in the course of four or five years.

THE additions to the Zoological Society's Gardens during the past week include a Malbrouck Monkey (*Cercopithecus cynosurus* ♂) from West Africa, presented by Mrs. East; a Sambur Deer (*Cervus aristotelis* ♂) from Madras, presented by the Officers 1st Battalion Essex Regiment; a Long-eared Owl (*Asio otus*), a Tawny Owl (*Syrnium aluco*), British, presented by Mr. Gen. E. Crisp; a Malayan Tapir (*Tapirus indicus* ♂) from Malacca, a White Stork (*Ciconia alba*), European, two Magpies (*Pica rustica*), British, deposited; two Calandra Larks (*Melanocorypha calandra*), European, purchased; five Striped Snakes (*Tropidonotus sirtalis*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

THE OCCULTATION OF ALDEBARAN ON FEBRUARY 22.—In the occultation of Aldebaran on the 22nd of the present month, the immersion takes place while the sun is above the horizon in this country, and the emersion soon after sunset. The following times and angles are founded upon the data of the *Nautical Almanac*, the angles being reckoned as in that work; the times are Greenwich mean times at the respective observatories:—

	Immersion	Angle from N. point	Emersion	Angle from N. point
	h. m.	°	h. m.	°
Greenwich	5 16·6	... 36	... 5 49·6	... 344
Oxford	5 13·3	... 40	... 5 49·7	... 341
Cambridge ...	5 14·9	... 41	... 5 52·6	... 339
Dublin	5 1·8	... 52	... 5 50·0	... 329
Liverpool	5 7·3	... 49	... 5 53·3	... 334
Glasgow	5 3·7	... 60	... 5 57·9	... 320
Edinburgh	5 5·3	... 59	... 5 59·1	... 321

VARIABLE STARS.—DR. Gould notifies the detection of three new variable stars at Cordoba, which he calls respectively R Lupi, R Piscis Austrini, and R Phœnicis. In his communication to the *Astronomische Nachrichten* he refers to his recently published zones for their positions, which, brought up to the beginning of the present year, will be:—

	R.A.	Decl.
	h. m. s.	° ′
R Lupi	15 46 1	... −35 57·2
R Piscis Austrini ...	22 11 28	... −30 10·7
R Phœnicis	23 50 29	... −50 45·6

By Argelander's formula of sines the last maximum of *Mira* should have occurred on January 28, but the maxima and minima of the last four or five years appear to have taken place between a fortnight and three weeks earlier than the dates assigned by the formula. Perhaps some reader of NATURE may be able to fix the time of the recent maximum from his own observations.

WOLF'S COMET.—The following ephemeris of Wolf's comet of short period is deduced from Herr Thraen's ellipse, which depends upon normal places to November 23. The comet was observed without difficulty at Lund on January 20:—

At 6h. Greenwich Mean Time

1885	R.A. h. m. s.	Decl. °	log distance from Earth	log distance from Sun

GEOGRAPHICAL NOTES

Commission which was originally appointed to investi- possibility of a maritime canal across the isthmus of the north of the Malay Peninsula, has continued its on in this unknown region. It is composed of M. accompanied at first by M. Paul Macey, Mr. Davidson, lish engineer, and a Siamese commissioner. Their visit to the place was made in the spring and summer ear. After ascending the peninsula from the isthmus to 7° 15′ 2″ latitude, and visiting the Samuil Islands, interesting and least known of the archipelagoes in the Siam, the expedition penetrated the peninsula to the Singora, 7° 14′ N. latitude, where they discovered the existence of a State, Sam-Sam, composed of mestizos, or half-caste Malays and Siamese, the former haunt of pirates and semi-independent of Siam. By wale and deep channels which enter far into the country, the party were conducted to a large inland sea, called Talé-Sab, which they were the first Europeans to visit. This was found to be about 6 metres in depth, and 45 miles long by 12 wide, of a curious configuration, with small islands covered with the nests of sparrows. The water is fresh during the north-east monsoon, but brackish during the south-west; it separates the peninsula properly so-called from the island of Tantalam (or Ko Yai in Siamese) by a number of *arroyos*, which stretch from Singora in the south to Lacon in the north. The party landed at Talloung on the west side, at 7° 40′ N. latitude, where a Sam-Sam rajah supplied them with elephants to cross the peninsula. They crossed a large plain under rice cultivation to the borders of Klong Talloung, then reached the chain of Lemang Mountains, which forms the end of the peninsula, and then descended the Tsang River, which flows into the Bay of Bengal. Three visits in all were made to these regions during the year, and the States of Tsang, Talloung, Lacon, Singora, and Stouil were thoroughly explored. The engineers have already made their geological reports of the whole regions, and certain specimens which have been analysed at the School of Mines in Paris shows that deposits of auriferous quartz, tin, and iron exist in this *terra incognita*. Numerous ethnographical observations were also made on the Sam-Sam, their government, and habits of piracy.

MR. A. R. COLQUHOUN has published a notice in the Eastern journals with regard to his projected exploration of the Shan States. His colleague, Mr. Holt Hallett, after consulting with him concerning the further exploration and survey of Siam and the Shan country, has left China for Bangkok, in order there to hold an interview with the King of Siam on the subject. He will thence proceed to Rangoon and Calcutta, to report to, and consult with, the Chief Commissioner of British Burmah and Lord Dufferin. From Calcutta Mr. Hallett will proceed to London to submit his reports to the Royal Geographical Society and the Chambers of Commerce which have supported the exploration survey. Any exploration on the southern frontier of China, such as was intended to be included, is for the present out of the question, owing to the unsettled condition of the frontier regions. The continuation of the explorations in Siam and the Shan country depends on the result of Mr. Hallett's visit to Siam and India. A preliminary report has been drawn up by Messrs. Colquhoun and Hallett, dealing with the first year's operations, which will be published on Mr. Hallett's arrival in England.

AT the meeting of the Geographical Society of Paris on the 23rd ult., M. Mascart president, M. Thouar, known for his journey in search of the remains of the Crevaux expedition, announced that he is about to start on his fourth journey in South America. His project is to ascend the Paraguay, and study the delta of the Pilcomayo, where Crevaux perished, and then to investigate the possibilities of a trade route between Bolivia and the Paraguay. M. Thouar will then carry out the mission with which he is charged by the Bolivian Government—viz. in company with some engineers and naturalists, to study the whole of Bolivia from scientific, industrial, and commercial points of view.—M. Cabres described some episodes of a journey which he recently made to Bokhara; and M. Rey presented to the Society a new map of the north of Syria, designed by M. Thaillier.

UNDER the title of "Un' Estate in Siberia fra Ostiacchi, Samoiedi, Sirieni, Tatari, Kirghisi e Baskiri" (Firenze, 1885), Signor Stephen Sommier describes a voyage which he made down the Obi from its confluence with the Irtish to its mouth in the Arctic Ocean. He made during the journey interesting observations on the course of the river, and on the temperature of the water. Towards the end of July the mean temperature was 18° above zero, even at the mouth of the river, and in August it was still + 10°. These have much importance for the question of the navigability of the Kara Sea. Under the influence of these masses of warm water, the coast ice should melt, and consequently the icebergs which have in recent years blocked the straits giving access to the Kara Sea cannot be of great extent. The most important part of the volume, however, is that devoted to the anthropology and ethnography of the Ostiaks and Samoyedes. On the course of the Obi are groups of habitations where travellers are supplied with rowers, and each time Signor Sommier changed his men—about a hundred times in

all—he made anthropological observations, and collected ethnographical objects. These are now in the Ethnographical Museum in Florence, and illustrations of a considerable number of them are found in his work. Besides these tribes, the book also deals with the Bashkirs and Kirghises, whom the author visited in returning to Europe.

THE last *Bulletin* (No. 6) of the Geographical Society of Belgium contains a paper by M. Oscar Royer describing his journey on the Congo; notes on a journey in Texas, by Mr. Lancaster; also "Some words on Atlantis," by M. de Bloek, who regards this fabulous region as merely one of those invented by the ancients for the purpose of working out in imagination their social and political theories. Finally, a study on the first narrative of Columbus, and the old printed editions of it, with a fac-simile of the first "Epistola C. Coloni," printed at Antwerp in 1493.

THE INSTITUTION OF MECHANICAL ENGINEERS

THIS Institution held its annual general meeting in London last week. The list of papers to be read we have already given, though some of them were not read; the only one calling for special notice at our hands is that of Sir Frederick Abel on a "Final Report bearing upon the Question of the Condition in which Carbon exists in Steel." The following are the conclusions which Sir Frederick bases on the present and on the two preceding reports:—

"The results of the experimental work described appear to warrant the following conclusions in regard to characteristics, recognisable by chemical examination, which are exhibited by different portions of one and the same sample of steel presenting marked physical differences consequent upon their exposure to the hardening, annealing, or tempering processes.

"(1) In annealed steel the carbon exists entirely, or nearly so, in the form of a carbide of iron, of uniform composition (Fe_3C or a multiple thereof), uniformly diffused through the mass of metallic iron.

"(2) The cold-rolled samples of steel examined were closely similar in this respect to the annealed steel, doubtless because of their having been annealed between the rollings.

"(3) In hardened steel the sudden lowering of the temperature from a high red heat appears to have the effect of preventing or arresting the separation of the carbon, as a definite carbide, from the mass of the iron in which it exists in combination; its condition in the metal being, at any rate mainly, the same as when the steel is in a fused state. The presence of a small and variable proportion of Fe_3C in hardened steel is probably due to the unavoidable and variable extent of imperfection, or want of suddenness, of the hardening operation; so that, in some slight and variable degree, the change due to annealing takes place prior to the fixing of the carbon by the hardening process.

"(4) In tempered steel the condition of the carbon is intermediate between that of hardened and of annealed steel. The maintenance of hardened steel in a moderately heated state causes a gradual separation (within the mass) of the carbide molecules, the extent of which is regulated by the degree of heating, so that the metal gradually approaches in character to the annealed condition: but, even in the best result obtained with blue-tempered steel, that approach, as indicated by the proportion of separated carbide, is not more than about half-way towards the condition of annealed steel.

"(5) The carbide separated by chemical treatment from blue- and straw-tempered steel has the same composition as that obtained from annealed steel.

"It does not appear that this inquiry can be further extended with the prospect of obtaining any additional facts—elucidating the condition of the carbon in steel exhibiting various physical characteristics—the value of which would bear any proportion to the very laborious nature of the necessary experimental work, which has to be conducted with small quantities of material on account of the necessity of carrying out the annealing, hardening, and tempering processes with very thin pieces of steel.

"I believe it will be admitted that, although the data obtained have not led to the discovery of a ready chemical method of differentiating between different degrees of temper in steel (a method of examination which Prof. Hughes's interesting results have almost rendered unnecessary), they have at any rate contributed to the advancement of our knowledge of the nature of steel."

THE INFLUENCE OF DIRECT SUNLIGHT ON VEGETATION

THE influence of direct sunlight on vegetation is generally known, but surely deserves to be a subject of special study. In the following paper we shall only endeavour to describe some facts with relation to this influence. In the first place, the effect of the sun's rays in the tropical regions will be traced, and afterwards in the temperate and arctic zones. The constant high temperature within the tropics is the cause of the plants being less dependent on the direct solar heat than is the case in the greater part of the temperate and cold zones, but, notwithstanding this, there are plants even in the tropical regions requiring for a luxuriant growth the direct rays of the sun.

Of the tropical monocotyledonous plants, the palms are doubtless the most important, and of these the date-palm of the Sahara Desert (*Phœnix dactylifera*, L.) furnishes daily food to the inhabitants of this part of Africa.

It is known that the subterranean wells are the only cause of vegetation in this desert. When a well is discovered, in a short time an oasis arises, and the date-palms appears.

Considering that the first condition for the growth of palms is a humid soil wherein the roots may vegetate, there seems to be at first something strange in the fact of the Great Desert producing species of this family; but the Arabs say that this "Queen of the Oasis" puts her feet in water and her head in the fire of heaven; and this is the cause of the rapid growth of the plant (Greisbach, "Die Vegetation der Erde," Theil ii. p. 371); the water ascends by the roots into the tissue of the tree, and communicates its temperature to the inner parts, so that the influence of the sun's heat is tempered; the evaporation of the plant also causes a lower temperature; thus it withstands a difference of 98° (from 126° to 28°), as occurs in the Desert (Martins, "Le Sahara," *Revue des deux Mondes*, 1864, vol. liii. p. 613).

Though, as we have said above, these plants require, in the first place, water for their roots, the fact of the stems growing in their wild state at a considerable distance the one from the other, and never forming dense forests, proves that they require also the light.

But the date-palm is indigenous to the Great Desert; nowhere else does this plant vegetate so rapidly. When cultivated with success, it is also in a desert-climate, as, for instance, in that of Murcia in Spain (the date forest of Elche), the highlands of Afghanistan, &c. The cause of its culture being without fruits in the Mediterranean is the dry summer, there being no subterranean wells, as is the case in the Sahara.

The sugar-cane (*Saccharum officinarum*, L.) is also a plant requiring the direct solar light; moist climates are disadvantageous to its cultivation. Thus the climate of China, with its heavy rains in May and June (Dove, "Klimatologische Beiträge," vol. I. p. 102), but less precipitation in autumn, when the fruits ripen, is suited for the culture of this plant. It is known that the quantity of sugar depends on the quantity of sunshine.

Turning to the warm temperate zone we see the species of *citrus* cultivated in the sunny climate of Southern Italy, and even by cultivation produce the delicious fruits generally known, because they are in summer under the almost constant influences of the sun's rays in open localities. In the Malayan Peninsula, the supposed native country of these plants, they also grow in open spaces and not in the jungles, requiring a moist soil, but also the solar light, to ripen their fruits; this explains why the finest and largest oranges are obtained when the trees are trained against walls, as is the case in some parts of Southern England.

The vine (*Vitis sinifera*, L.) is also a plant requiring heat in the after summer to ripen its fruits; the climate of Southern France and Italy is therefore well adapted for its cultivation. In the continental climate of Bokhara in Turkestan (40° N. lat.), with its hot summers (in the sandy desert on the Oxus River the soil was found to have a temperature of 144°—Bastner, "Reise durch die Kirgisensteppe nach Chiwa"), the plant is cultivated in the open fields; its winter covering is not taken off before the end of March, but in April the temperature is already very high, and in July it becomes insupportable;[1] the fruit of the vine is ripe by the end of June or the beginning of July. The soil is moistened here by artificial irrigation. A

[1] Mean temperature at Samarkand, for 29° 52′, in 1881: April 61°, May 70°, June 77°, July 81°, August 77°, September 66°, and December 28°; mean temperature at 1 p.m. in June 86°, in July 93°, in August 92°, in September 84°.

logical Service in Canada.

In the vicinity of the arctic zone the influence of insolation is, in the first place, observed on the Continent. At Turuchansk, lat. 65° 55′, gourds are cultivated, though of a small size (Middendorff, "Sibirische Reise," band iv. theil i. p. 701). The mean temperature in 1881 was: Of June 48°, of July 59°, and of August 55°, the two last months being about equal in temperature to the means of Valentia in Ireland, lat. 51° 55′ (July 59°, August 59°); but at Turuchansk there were, in June, 7 days with the temperature, at 1 p.m., ranging between 68° and 73°; in July, 15 days ranging between 68° and 82°; and in August, 16 days ranging between 62° and 75°. Number of days completely clouded: June 6; July 9; August 3. Snow did occur till June 15, and was observed again on August 29 (*Annalen der Physikalischen Central Observatoriums*, St. Petersburg). In Norway the cultivation of gourds (*Cucurbita Pepo*, L.) reaches 59° 55′.

In North America, at Cumberland House, lat. 53° 57′, a sugar harvest is collected from *Negundo fraxinifolium*, Nutt. (*Acer negundo*, L.), by means of cuttings in the trees, but the flow of the sap is greatly influenced by the action of the sun's rays, and is greatest after a smart night's frost (Richardson, "Search Expedition through Ruperts Land," vol. ii. p. 236).

In summer, the influence of the direct sunlight causes the tropical mid-day temperature so common in the interior of both continents in the temperate zone; but in America the days' differences are much greater than in Asia;[1] even near the eastern shores (Montreal, Quebec, &c.) daily differences of 20° are of common occurrence in midsummer.

The Asiatic continent, reaching to the Arctic Sea, without interruption presents to the sun's rays a much greater surface than is the case with America, where the melting ice in Hudson's Bay and the Arctic Archipelago consumes the greatest part of the solar warmth, being at the same time the cause of the sudden low temperatures occurring when the wind turns to the north or north-west.

Notwithstanding this, the European vegetables and corn are cultivated with success in the United States and the interior of Canada, but some of them cannot stand the sudden changes of temperature, as, for instance, the vine, and also the orange-tree (*Citrus aurantium*, L., et varr.); the general cultivation of the latter does not reach beyond 30° N. lat. (Florida).

Nowhere else is the influence of insolation more distinctly observed than in the arctic regions. It is known that in high latitudes the heat of the sun's rays in summer is often very great. Richardson remarks that (being under about 60° N. lat. near the Slave River) he had never felt the heat within the tropics so oppressive as he experienced it on some occasions in these arctic regions (Richardson, "Search Expedition," vol. i. p. 144), though the sun's rays are here always horizontal instead of vertical, as is the case in the tropical countries. The enormous multitude of mosquitoes suddenly appearing in spring when the ice is thawing, and in places where there is water for their larvæ (swamps, pools, &c.), is also much greater than in India.

The observations on the following page may give some idea of the difference between the temperature in the shade and that in the sun's rays.

At Fort Franklin, Great Bear Lake, North America, lat. 65° 12′, the mean temperature in the last part of March or the beginning of April is about 0° F.; the effect of the sun's rays on the blackened bulb of a thermometer, however, is sufficient to raise the mercury to 90° (Richardson, "Search Expedition," vol. ii. p. 254).

Comparing these observations with those within the tropics we see that the difference between the maximum temperature in the sun in these regions and the northern is relatively small. Maximum temperature in the sun, 1882: Calcutta, 162°; Bombay, 151°; Colombo (Ceylon), 157°; Barbadoes, 156°. But in dry climates the difference is greater: Melbourne, 109°; Adelaide, 180°. The mean humidity at Adelaide was only 58 per cent.; highest temperature in shade 112°.

Even in the North American Arctic Archipelago, in Smith Sound, lat. 78° 30′, where the mean summer temperature is only 33° (June 30°, July 38°, August 31°), Kane's observations with the black bulb thermometer gave the following results:—

[1] Greatest difference at Winnipeg, lat. 49° 25′, on July 6, 1881, maximum 98°, minimum 45°; difference 53°. At Poplar Heights, Manitoba, lat. 50° 5′, maximum on May 10, 76°, minimum 29°; thus difference 50°. At Blagowestchensk, Siberia, lat. 50° 15′, on May 23, 1881, maximum 79°, minimum 48°; difference 31°. At Akmolinsk, lat. 51° 12′, on May 25, maximum 88°, minimum 30°; difference 58°.

From May 16 till September 4 the temperature in the sun's rays was constantly above the freezing-point (with exception of May 22, when this was not the case); on June 15 it reached 48°, on the 26th 54°, on July 5, 70°, and on August 11, 66°.

Observations at Pandow 2k, Russia, Lat. 59° 43'[1]

It is clear that the influence of the sun's rays increases with higher latitude, because the sun in summer rests above the horizon.

Now we come to the main point, viz. the effect of the direct solar heat on vegetation in the northern regions.

In Novaya Zemlya the vegetation (consisting chiefly of herbaceous plants) is, in places exposed to the sun's rays (at the foot of mountains), like an arctic flower-garden, the surface of the soil not being covered with grass as is the case in the temperate regions. The flowers are here of a much greater size than the leaves. In this island, and even in Spitzbergen, the snow disappears in summer by the action of the sun from hills exposed to its light; but on Ben Nevis in Scotland, being a difference in latitude of more than 20°, the snow rests sometimes the whole year.

In the Tundra of Siberia, on the declivities of hills sheltered from the winds and exposed vertically to the sun's rays, the same herbaceous vegetation, with its large, splendid-coloured flowers, is observed (Middendorff, "Sibirische Reise," bd. iv. th. i. p. 733), but this is not the case in plains where the sunlight in its horizontal direction cannot have so much influence on the vegetation of the frozen ground; therefore these plains are in general really deserts, only covered with moss.

Insolation is also the cause of the rich vegetation in some parts of the mountains in the temperate zone (Alps, &c.).

Even in the most northern regions there can be a rich vegetation where the plants in sheltered localities are exposed to the sun. Parry [" Attempt to reach the North Pole") found the scurvy grass (*Cochlearia*) on Walden Island under 80° 30' N. lat. in such a luxuriant growth as he had never seen it before.

Middendorff observed, under 74° 30' N. lat., on the borders of Lake Taimyr in Siberia, on August 2, a temperature of 52° in the shade; but a heliothermometer under glass placed in the sun's rays stood at 104°; an uncovered one marked, in the sun, 70°. The pitch on his boat was not only melted by this temperature, but flowed (Middendorff, "Sib. Reise," p. 657).

But, as is the case also in lower latitudes, the greatest difference between the temperature in the shade and in the sun occurs in early spring. In June, Middendorff was travelling in the Stanowoi Mountains, and saw a rhododendron in full flower; when he was about to gather some flowers of this plant he found not only the roots, but even the stem, frozen hard in the soil. The temperature of the air was between 54° and 43°, but at night it was some degrees below freezing-point.

The assertion of some botanists that the contents of the cells, as soon as they are frozen, make the latter burst, thus causing the death of the plants, has been already refuted by Nägeli; but the important observations of Middendorff have showed clearly that the severest frosts of the Asiatic cold pole, by which the innermost parts of the trees are frozen as hard as iron, have little influence on the tissue when the cold becomes *gradually* more intense; only *when the temperature sinks suddenly below the freezing-point of the mercury* the wood splits with a thundering noise. These crevices have a disadvantageous influence on the vegetation of the tree in summer, because in these places the plant often begins to rot.

The trees rest in a frozen state till, in spring, the sun's rays reach the upper parts, and here vegetation is raised, though the roots and lower parts of the stem are still in a frozen state.

But the most interesting discovery on this subject was made by Middendorff under 69° 30' N. lat., on April 14, near the village of Dudino; notwithstanding the clear sky and incessant brilliant light of the sun, the temperature at mid-day ranged from −4° to −13°, yet before and after this time from −24° to −35°. While going over the glittering snow he was suddenly stopped by the sight of a willow-catkin peeping about an inch out of it. The catkin was wholly developed, yet the branch on which it was observed was, one or two inches down, solidly frozen; this was also the case with the other parts of the plant hidden under the snow (Middendorff, p. 653). Thus this little part of a branch was called to life, for some hours only, by the direct solar rays, in which it was thawed.

In the beginning of August, under lat. 74° 30', Middendorff found the soil exposed to the sun's rays heated to 86°, though the temperature about four inches below the surface was only 39°, and at the depth of about one foot the ground was constantly frozen (Middendorff, p. 666).

It is clear that plants in the high northern regions, when they vegetate, receive more warmth by insolation than is often supposed—1° by the direct solar light itself, and 2° by the heated surface of the ground. The snow and ice being melted by the sun, the necessary water and humid atmosphere never fail; even this is the cause of the luxuriant growth of grass on some places of the Tundra. The flowing water gradually communicates its warmth to the soil, and prevents also the nightly radiation.

All this is proof enough that, when the mean temperature in shade is known, this is not at all sufficient for a knowledge of the real temperature by which the vegetation of several plants is raised. What might have been the temperature in the tissue of the little branch and also in that of the willow-catkin, of which we have spoken? And this when the temperature in the shade was so many degrees below freezing-point.

In the temperate regions vegetation commences in spring, when the difference of temperature between night and day is greatest; in the high north this difference is often insignificant, because the sun rests above the horizon; but the temperature of the soil being at this time very much lower than that of the objects exposed to the sun's rays, even this great difference is the cause of the very rapid vegetation in sheltered localities and under the influence of the solar light.[2]

In conclusion we must remark that the facts thus briefly mentioned show how much a new system of bio-meteorological observations is wanted to ascertain the real quantity of warmth and sunlight necessary for the growth of plants, many of which are of the utmost importance in the life of man.

M. Butsman

NEW ORGANIC SPECTRA[3]

THE absorption-spectra to be described were detected by means of the microspectroscope, and most of them are only fully visible in it, as the dispersion of the chemical spectroscope is too great for the detection of some of the very feeble bands. A binocular microscope provided with a substage achromatic condenser, to which are fitted two diaphragms, was specially made for this kind of work. Its objectives are so adapted as to enable both fields to be fully illuminated when any power up to the one-eighth is used. The left-hand tube is used as a "finder," and as a means of getting any required portion of the object into the centre of the field so that its spectrum may be obtained in the spectrum eyepiece of the right-hand tube. In this way the various portions of a very small bit of tissue or organ may be readily differentiated from each other and

s. The bands are carefully measured and compared

g all the vertebrate animals which I have yet examined.
hese precautions had been taken to exclude the influence of the
described in the demonstration.

with spectra yielded by various organs and tissues of Vertebrates, and no difference is found between those of Vertebrates and Invertebrates. In order to see these spectra in the higher animals the blood-vessels are washed out with salt solution thoroughly, and then the organs and tissues examined in the manner described. It is not possible to go into this subject in an abstract, as the facts are too numerous to be compressed into such a small space; it will suffice to say that the histohæmatins are respiratory pigments, as can be proved by oxidising and reducing them in the solid organs. Their bands occupy almost the same place as those of myohæmatin, except that the second and third bands of the myohæmatin spectrum appear compressed into one in some cases.

Myohæmatin itself is also undoubtedly a respiratory substance.

Spectrum of the Supra-renal Bodies.—In the supra-renals of man, cat, dog, guinea-pig, rabbit, ox, sheep, pig, and rat, the medulla gives the spectrum of hæmochromogen, while the cortex shows that of a histohæmatin. Wherever we find hæmochromogen in a vertebrate body it is probably excretory, and I have only found it in the bile and in the liver. Hence, and owing to the remarkable darkness of its bands in the medulla of the adrenals, it must be looked upon here as excretory; if so, the function of the adrenals must be (at least in part) to metamorphose effete hæmoglobin or hæmatin into hæmochromogen; if from disease, or after removal, as in Tizzoni's experiments, the effete pigment is not removed, pigmentation of skin and mucous membrane may take place. The presence of taurocholic acid in the medulla (Vulpian), the resemblance in the structure of the adrenals to that of the liver, and the large lymphatics, with the well-known results of disease of the adrenals in Addison's disease, all go to show that an active metabolic process is taking place in them, and I believe I am justified in concluding that they have a large share in the downward metamorphosis of effete colouring matter, and that these observations will help to throw some light on Addison's disease.

SOUTH GEORGIA

SOME interesting particulars of the geography, climate, &c., of the island of South Georgia have recently been published by the members of the German Expedition which sojourned in 1883 at the island. They are of the more interest as no scientific expedition had previously visited the island, of which but little therefore is known. The Expedition, in command of Dr. Schrader, took up their quarters at Moltke Hafen, in Royal Bay, which is from four and a half to five miles wide and from six to eight miles long; here observations were made from September 15, 1882, until September 3, 1883, when the Expedition left in a German gunboat. The 8472 observations made during this period on the temperature, air-pressure, moisture, wind, &c., are of great importance.

The island is by its position (54° 31′ S. lat. and 36° 5′ W. long.) not an Antarctic island in the strict sense of the word, but its appearance stamps it as such—Royal Bay being surrounded by mountains, with enormous glaciers from 900 to 1200 feet in height, which further inland rise to 6000 or 7000 feet. This circumstance may give some idea of the climate, and it is therefore not surprising to learn that the mean temperature of the whole period of observation was only 35° F.; for February, the warmest month, 42°, and for the coldest (June) 26°·6. No single month was free from frost, and 30 per cent. of the hours of observation showed a temperature below freezing-point. In July the minimum-thermometer registered 26°·2, and in February the maximum-thermometer 57°·2, the range of temperature amounting to 31°. Clear days occurred in the winter only, the total number being 8; whereas the total of cloudy days was 127; the latter were less frequent in July and August. During December not a single day was clear, and the total number of hours of clear sky was only 269, against 1302 which were cloudy, *viz.* 38·9 per cent. of the total. Consequently there was much rain and snow, particularly in November and December, which had only one dry day each. Most snow fell in March and least in May. Even the warmest month, February, had 13 days with snow, while the coldest, June, had four days with rain. It hailed on 19 days, principally in December; there were 75 days of fog, but it did not last long. As regards winds and storms, the observations of the Expedition seem to indicate that the neighbourhood of Cape Horn is not quite so stormy as is generally believed. At South Georgia there were

many days of perfect calm; the summer was, however, more stormy than the winter. The winds came chiefly from the west—those from a due westerly direction being most common—and also from west-south-west or north-west. The westerly and south-westerly winds were during the winter the warmest, which is ascribed to the circumstance that they passed over mountains some 6000 feet in height, which rendered them "Föhn-like." The barometer readings were never attended by violent storms; these occurred without exception when the glass stood at "fair." There was no aurora australis, nor were there any thunderstorms.

Explorations of the island were undertaken on several occasions, and many of the peaks in the neighbourhood of Royal Bay were climbed. The slate rocks were very difficult of ascent. The enormous glaciers in the mountains of the interior prevented, unfortunately, any thorough exploration of this part. The mountains often sloped abruptly into the sea, and the highest points were about ten miles from the station and covered with eternal snow. The roar of avalanches was continually heard. The fauna was very poor. That such a dreary climate should boast of a very extensive fauna or flora was hardly to be expected; nevertheless, the mosses were very fine. Dr. H. Will, the botanist, collected about thirty varieties. They show what a climate where the sun is nearly always absent can produce in the way of plants which are able to resist rapid changes of temperature, but the fauna is one which may at once be said to belong to more Antarctic regions than Terra del Fuego, the Kerguelen Islands, and more northerly places. It is a repetition of the same types, with originality in details alone.

CARTOGRAPHICAL WORK IN RUSSIA

WE learn from a recent issue of the *Izvestia* of the Russian Geographical Society that the following geodetical and cartographical work was done during the year 1883 by the officers of the Russian General Staff. The first-class triangulation for connecting the line of Warsaw and Grodno with that of the Vistula was continued; the secondary network of triangulation was extended in Lithuania and Poland; and the heights of 262 places were determined by careful levellings. The most useful work of exact levellings on the Russian railways, undertaken several years since, was continued in West and South-West Russia, leading to a precise measurement of the differences of level between the Baltic and the Black Seas, and the final results are now being calculated. The Russian survey was continued on the scales of 1400 and 1750 feet to an inch, in Poland, Lithuania, Bessarabia, and Finland; and a most welcome feature of it is that great attention was given to the measurements of heights, so that a map with level-lines only, 35 to 70 feet apart from one another, may be published. In the Caucasus very accurate measurements of the latitudes and longitudes of Tiflis, Baku, and Shemakha were made, as also pendulum observations in Trans-Caucasia. Of trigonometrical measurements, the triangulation of the Trans-Caspian region was continued as far as the Persian frontier, and that of Akhal-Tekke, was also calculated. An interesting feature of this last was the measurement of two geodetical bases on strings—which method gives, as is known, very satisfactory results—together with a much greater economy of time. Detailed surveys were continued in several parts of the Caucasus, those at Askabad, and between Kyzil-Arvat, Bami, and the Sumbar River (two versts to an inch) being especially worthy of notice.

In Turkestan, at the Tashkend Observatory, Col. Pomerantseff continued his observations of minor planets with the refractor of the Observatory, and the measurement of stars by means of the meridian-circle; and his assistant, Capt. Zalessky, regularly made measurements of occultations of stars by the moon. The work of the Observatory will soon be published, and will contain an elaborate paper by Dr. Schwartz, on magnetism in Turkestan. Several most valuable determinations of latitudes and longitudes were made by M. Putyata in the Pamir during M. Ivanoff's expedition. Among many surveys which were made this year, that of the northern slope of the Turkestan ridge was especially interesting, no less than twenty-three unknown glaciers having been discovered at the sources of the Sakh, and mapped. The Shemanovsky glacier, eight miles long, and that of Ak-terek, twenty-two miles long, which joins the well-known Zarafshan glacier, are especially worthy of notice. A survey of the rich oasis of Karshi, and of the Bokhara dominions on the right bank of the Zarafshan, is also very interesting. The map of Turkestan on the scale of ten versts (seven miles) to an inch, is already in print, and several sheets are nearly ready.

In the Omsk military district we notice several determinations of latitudes and longitudes, as also the survey of the Kirghis Steppe, on a scale of five versts to an inch. In Eastern Siberia the chief work was the further extension of the triangulation of Trans-Baikalia—a most necessary work, on account of the scarcity of determined points to fix the surveys in that region—and many local surveys, those in the Usuri region and on the Pacific coast being especially interesting. The astronomically determined points, very few on the whole, have received only seven additions.

The Hydrographical Department has pursued its work on the Baltic, the Black, and the Caspian Seas, as also on some lakes in the interior of Russia and Finland; the most interesting of them being several detailed maps of the Lake of Onega, and the Lakes Päyanne and Pielis, in Finland; the triangulation and surveys on the Caucasian coast of the Black Sea; and the survey of the Gulf Mortvyi Kultuk of the Caspian.

Among the publications of the General Staff we notice the thirty-ninth volume of its *Memoirs*, which contains the following papers:—On the triangulation of Bessarabia, by Col. Lebedeff; on the difference between the longitudes of Tashkend and Vernyi, by Col. Pomerantseff; on astronomical determinations made in Trans-Baikalia (fifty-two places), by Capt. Polanovsky; in the Altay region and in West Siberia (thirteen places), by Col. Miroshnitchenko; in the Trans-Caspian region (with a map), by Col. Gladysheff; and in North-West Mongolia, by Lieut. Kafailoff; on levellings on Russian railways; on the determination of time by means of the meridian-circle, by M. Gladysheff; on the Trans-Caspian triangulation (ninety-two places), by Capt. Pervas, in which it is stated that Askabad is 827 feet, and Mount Riza, on the Persian frontier, 9741 feet, above the sea-level; and finally, a description by Col. Alexandroff of the route from Kungrad to the Gulf of Mortvyi Kultuk, the distance being 300 miles, of which about 90 miles are without water.

The Annual Report of the Hydrographical Department contains seven small maps showing the exact results of the surveys made on the Russian coasts up to 1882; and a paper by M. Golovinin gives at the same time a sketch of the hydrographical work done by the Russian fleet since its first formation in 1696.

SCIENTIFIC SERIALS

IN the *Journal of Botany* for January Mr. H. N. Ridley describes and figures the extremely rare *Juncus tenuis*, a plant entirely lost to Britain since 1795 or 1796, when it was gathered by G. Don in Clova, till 1883, when it was rediscovered by Mr. Townsend in Herefordshire. Mr. W. H. Beeby records another interesting addition to the British flora in a new *Sparganium*, which he names *S. neglectum*, nearly allied to *S. ramosum*, and probably a sub-species of it, found in ponds in several parts of Surrey.

THE last part of the *Belgique Horticole* that has reached us, that for May and June 1884, contains but little that is original, the substantial articles being taken from French, German, or English journals. The coloured plates of new or little-known plants, with accompanying descriptions, are of their usual excellence, and there are many short paragraphs of interest to horticulturists.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, January 29.—"On some Physical Properties of Ice and on the Motion of Glaciers, with special reference to the late Canon Moseley's Objections to Gravitation Theories." By Coutts Trotter, M.A., Fellow of Trinity College, Cambridge. Communicated by Prof. Stokes, Sec. R.S.

Canon Moseley's theory of glacier motion, put forward in 1855, has never been accepted by persons conversant with glaciers. In 1869, however, he put forward a somewhat formidable objection to the current gravitation theories of glacier motion.

The gist of the objection is that the resistance of ice to shearing is many times greater than the shearing force which can be produced in a descending glacier by gravity; and that therefore the shearing which the measurements of Forbes and

ave shown to be an essential part of the motion of a
cannot be produced by gravity alone.
s pointed out at the time that in Moseley's experiments
shearing strength of ice the element of time had been
ded, and a number of experiments have been since pub-
chiefly on the bending of pieces of ice under the influence
own weight, which showed conclusively that the con-
action for a considerable time of comparatively small
ill produce effects upon ice which the same forces are
capable of producing in a short time. The nature and
ns of the motion were, however, very different from those
re meet with in a glacier.
r these circumstances it seemed desirable that fresh
experiments on the shearing strength of ice should be
nder conditions differing as little as might be from those
hich ice actually shears in the interior of a glacier, and
red to me that such experiments might be advantageously
a one of the artificial grottoes which are now excavated
er year for the benefit of tourists in several of the more
de Swiss glaciers. It seemed that it would be possible
way to carry out experiments upon glacier ice at a nearly
temperature of about 0° C., and under conditions as
esembling those of the interior of a glacier as we can
attain to in experiments on hand specimens of ice.
ordingly spent part of the long vacation of 1883 at
wald, and made a series of experiments in the grotto on
ie bank of the lower glacier, in order to see whether I
btain direct evidence of shearing under the influence of
omparable with those which Canon Moseley admits to
ible of being produced by the action of gravity in a
glacier.
experiments are fully described in the paper. Bars of ice
assed through holes in three parallel blocks of wood,
in contact with one another. The two outer blocks were
o a frame and a weight was suspended from the middle
After the whole had hung for some days, the apparatus
ken to pieces and the shear measured. In a final experi-
shear of about ·075 cm. was observed after the action for
seventeen days of a shearing force of rather more than
o. per square centimetre.
shearing force employed was indeed rather more than
that which, according to Canon Moseley's calculations, is
by gravity in the Mer de Glace, near the Tacul (*Phil.
xxvii. p. 369); but it is about 1/25th of his smallest
f the shearing strength of ice, and the amount of shear is
han is implied in any of the ordinary cases of glacier
.
nk then that there is little doubt that under conditions
resembling those of the interior of a glacier, and under
uence of forces comparable with those which gravity is
of exerting in a glacier, hand specimens of ice shear in
ie manner as a truly viscous solid would do.
ons are given for supposing that the range of temperature
which ice is sensibly viscous is small; the temperature
interior of a glacier is discussed, and it is pointed out
position of the "Bergschrund" so familiar in Alpine
re corresponds to a point where there is a change in the
ature of the lower part of the glacier, all below the
schrund" being soft and viscous, all above it hard frozen
movable.
general result of the foregoing paper seems to be that the
nsideration of the physical properties of glacier ice leads
tially the same conclusions as those to which Forbes was
y years ago by the study of the larger phenomena of
motion—that is, that the motion is that of a slightly
mass partly sliding upon its bed, partly shearing upon
der the influence of gravity. To say this is, however,
means to deny the importance of regelation in the
y of a glacier. To regelation mainly we must attribute
inal passage of snow through the form of *névé* into ice,
ling of crevasses, and the possibility of comparatively
id violent changes of form in portions of a glacier in
nusually powerful forces may be supposed to be at work.
's argument, however, seems to be decisive against the
at the ordinary comparatively undisturbed descent of a
ng a moderately sloping bed takes place by fracture
elation. Moseley's value of the shearing strength of ice,
as been shown to be enormously too great as a measure
e instance of ice to slow shearing, would appear on
hand to be an inferior limit to the resistance to the
fracture which must precede regelation.

Royal Society, January 29.—"On the Structure and Rhythm of the Heart in Fishes, with especial reference to the Heart of the Eel." By J. A. McWilliam, M.D., Demonstrator of Physiology in University College, London. (From the Physiological Laboratory, University College.) Presented by E. A. Schäfer, F.R.S.

The eel's heart presents some peculiarities in structure. The auricle and ventricle are separated by a canalis auricularis. The ventral wall of the sinus venosus does not end in the proper auricular tissue but passes on to be attached directly to the ventricle. The superficial part of the ventricular wall is supplied by a special system of blood-vessels.

When the ventricle is faradised, it is found that a slowly-interrupted current (*e.g.* 3 per second) has a much more powerfully stimulating effect than a rapidly-interrupted current (*e.g.* 50 per second) of precisely the same strength.

The inhibitory effects of stimulation of the vagus nerve-trunk are very powerful; the accelerating after-effects are slight and variable. Vagus stimulation exerts no *direct* influence on the ventricle; it profoundly affects the auricle and sinus. It temporarily abolishes the excitability of the auricular muscle and of the muscular tissue entering into the composition of the ostial part of the sinus.

The manner in which the heart's action recommences after vagal inhibition is peculiar; the interjugular part of the sinus and the ventricle beat before the auricle and the ostial part of the sinus begin.

The passage of a weak interrupted current through any part of the auricle causes that part to stand still while the rest of the auricle goes on beating. Curare obviates the occurrence of this localised inhibition.

Physical Society, January 24.—Prof. Guthrie, President, in the chair.—Messrs. J. Rose Innes, A. Howard, and A. M. Worthington were elected members of the Society.—Some lecture experiments on spectrum analysis were shown by Mr. E. Clemenshaw. The chief point in these experiments was the production of a brilliant light without the use of the electric arc. A small quantity of a solution of the salt to be experimented on is put into a flask in which hydrogen is being evolved by the action of zinc upon dilute sulphuric or hydrochloric acid; the bottle is provided with three necks, one being fitted with an acid funnel, one with a jet, and by the other is introduced a current of coal-gas, or better, of hydrogen, by which the size of the flame can be increased and regulated. The jet, which is about one-eighth of an inch diameter, is surrounded by a larger tube, by which oxygen is admitted to the flame, the result being a brilliant light giving the spectrum of the substance, which is carried over mechanically by evolved hydrogen. The spectra of sodium, lithium, and strontium were shown upon the screen, and the absorption of the sodium light by a Bunsen flame containing sodium was clearly seen.—An instrument to illustrate the conditions of equilibrium of three forces acting at a point was exhibited by Mr. Walter Baily. This instrument consists of a circular disk of soft wood from the back of which an axle projects. The disk is provided with a graduated circle, and its centre marked by the intersection of two fine lines upon a small mirror. Three compound threads, each consisting of two threads connected by a short piece of elastic, are knotted together, the free end of each being fastened to a pin. Two of these pins are stuck into the disk at such a distance from the centre that the knotted ends cannot reach the centre without stretching each thread, and the remaining pin is then adjusted so that this condition is fulfilled. There are now three forces in equilibrium acting at the knot. The angles between their directions are obtained from the readings of the graduated circle where it is crossed by the threads. To determine the magnitude of these forces, the axle of the disk is held horizontally and turned till a thread is vertical; the pin is then removed, a scale-pan attached to the end of the thread, and weights added till the knot is brought back to the centre. This is repeated with the other threads. It was found possible to show the proportionality of the forces to the sines of the opposite angles with an error not exceeding 1 per cent.—Mr. C. H. Hinton read a paper on the "Pologram." As the result of a process of metaphysical reasoning, Mr. Hinton has come to the conclusion that relations holding about "number" should be extended to space. Starting from the premiss that the relation of a number to a number is a number, *e.g.* the "relation" of 6 to 2 is 3, the author proceeds to carry these principles into the consideration of space, and concludes that, when properly understood, the relation of a

e. south of it, with a broad, shaded, bright band between it nd the ring, which was so shaded as to give the appearance of swelling round the equatorial part of the planet.—On the sults of analyses of milk, cream, and butter at a recent dairy ow, by R. J. Moss, F.C.S. Cream obtained by the separator as found to be very much richer in "solids, not fat," than eam obtained by the ordinary process of skimming. Butter ade by different dairy-maids from the same cream and under entical conditions was found to vary chiefly in casein. The inimum quantity of casein found in this butter was 0·32 per nt., the maximum 1·17 per cent. It was observed that the ecimens that received the highest awards from the judges were se that contained most casein.—A new form of ammonium loride inhaler was exhibited by A. M. Vereker.

Natural Science Section.—On *Peachia hastata* (Gosse). rt i., description and habits, by Prof. A. C. Haddon and Y. Dixon. A description of the form, colour, and markings, d the variations of the conchula of specimens recently found Dublin Bay, and an account of its habits supplementing that Gosse.—Canadian, Archæan, or pre-Cambrian rocks, with a mparison with some of the Irish metamorphic rocks, by G. Kinahan, M.R.I.A.—Notes on apatite from Buckingham, awa Co., Canada, by G. H. Kinahan, M.R.I.A.—A set of usical stones from Cumberland, now in the Science and Art useum, were exhibited and described by B. H. Mullen. ecimens showing the mode of occurrence of *Sclerotium varium*, rkeley, were exhibited by T. Carroll.—The communication *Halcampa Andresii*, November 17, was by Prof. A. C. ddon.

SYDNEY

Royal Society of New South Wales, December 3, 1884. H. C. Russell, B.A., President, in the chair.—Sir George dell Airy, K.C.B., F.R.S., &c., and Prof. John Tyndall, C.L., F.R.S., &c., were elected Honorary Members; three w ordinary Members were also elected.—The Society's medal l 25*l.* were awarded to Mr. W. E. Abbott, of Wyngen, for essay upon "Water Supply in the Interior of New South ales." None of the papers upon "Origin and Mode of Occurce of Gold-bearing Veins and of the associated Minerals," or On the Infusoria peculiar to Australia," were considered of fficient merit to be awarded the prize. No communication s received upon "Influence of the Australian Climate in procing Modifications of Diseases."—The following papers were ad:—Notes on Doryanthus, by C. Moore, F.L.S., illustrated specimens of a new species.—Notes upon a new self-registerg anemometer, by H. C. Russell, B.A., F.R.A.S.—Waterpply in the interior of New South Wales, by W. E. Abbott. Mr. C. S. Wilkinson, F.G.S., exhibited some experiments to strate the nature of comets and to explain the reason for the l being usually turned from the sun.

December 17, 1884.—H. C. Russell, B.A., President, in the air.—Mr. Caldwell exhibited specimens illustrating his rearches into the embryology of the Marsupiala, Monotremata, d Ceratodus.

PARIS

Academy of Sciences, January 26.—M. Bouley, Presint, in the chair.—On the limit of accuracy in the differential rmulas employed in the reduction of meridian observations, M. M. Lœwy.—On the chemical neutrality of the salts, and the use of colouring substances in the quantitative analysis of e acids, by M. Berthelot. In the present paper the author roposes to generalise the results already obtained in the use of veral new colouring substances endowed with special properes of late years introduced into the process of chemical analysis. ie gives the thermic interpretation of the effects distinguishing ese substances, which are acids and salts whose proper reacons are determined by the laws of saline statics.—Note on the yro-electricity of the topaz, by MM. C. Friedel and J. Curie. rom their experiments the authors conclude that the crystals of opaz possess not only the already determined pyro-electric verical axis parallel to the axis of the prism, but also a horizontal xis of pyro-electricity present at least in some specimens exained by them. But, owing to the limited number of these pecimens, it is impossible clearly to define the position of the orizontal axis. The intensity of the electricity developed aries with the specimens themselves, in some of which the two xtremities of the axis are of like sign, which may be explained y the existence of superimposed hemitropic lamels.—Note on he modifications produced in the chemical composition of certain ecretions under the influence of epidemic cholera, by M. Gabriel Pouchet.—On the development of the egg of *Phylloxera punctata*, which infests the *Quercus sessiflora*, by M. V. Lemoine.—Chief results of the examination made at Toulouse during the years 1876-1883 of the observations of Saturn's satellites, by M. B. Baillaud.—Discussion of the results obtained with the Daguerrotype pictures of the French Commission appointed to observe the Passage of Venus in 1874, by M. Obrecht. The author concludes that the parallax of the sun, as deduced from the observations made by MM. Baille and Gariel, is found to vary between 8″·77 and 8″·33. This coincides with the 8″·66 with a probable error of 0″·06 already obtained by M. Bouquet de la Goye from the same data.—Results of the observations of the solar spots and faculæ made during the last quarter of the year 1884, by M. Tacchini. The results for the whole year, as compared with 1883, show that the period of greatest solar activity comprised the eight months from October, 1883, to May, 1884.—On a class of partially derived equations of the first order, by M. E. Picard.—On a special case of reduction in linear equations of the fourth order, by M. E. Goursat.—On the forms capable of integration in linear equations of the second order, by M. R. Liouville.—On the phenomena of condensation which take place in steam-engines during the period of admission, by M. F. Delafond.—Remarks on the dangers incidental to mechanical generators of electricity, and on the best means of avoiding them, by M. A. d'Arsonval.—On the ammoniacal sulphates of zinc, and on a means of separating a purely aqueous solution into two distinct layers, by M. G. André.—On the heat of formation of the sulphite and bisulphite of ammoniac, by M. de Forcrand.—Remarks on the cardiac hypertrophy occurring during the period of growth, usually between the years eight and twenty-one, by M. Germain Sée.—On the differential morphological characters of the young colonies of comma-bacillus cultivated in gelatine, by MM. Nicati and Rietsch.—Analysis of a chrysotile (a fibrous serpentine presenting the appearance of asbestos); a silica resulting from the action of acids on serpentine rocks, by M. A. Terriel.—Note on the geological phenomena produced by the earthquakes that took place in Andalusia from December 25, 1884, to January 16, 1885, by M. A. F. Nogués. A description is given of the crevasses, landslips, upheavals, subsidences, and other remarkable phenomena accompanying these disturbances.—M. Prestwich was elected a member for the Section of Mineralogy in the place of the late Signor Sella.

BERLIN

Meteorological Society, January 6.—Prof. Müttrich gave a short historical review of the arrangements in connection with forest meteorological stations in Prussia, seventeen of which were in operation. They were established on as uniform a system as possible over regions of very wide varieties of climate: on plains and at different levels above the sea, in districts having a more continental, and in districts having a more oceanic, climate, and in leaf and pine forests. In all these places, moreover, observations were made according to precisely the same regulations. Each station was twofold, having one equipment in the wood, another in the open field; both, as a rule, at a distance of 200 metres from the edge of the wood. The observations comprised the atmospheric pressure, the temperature of the air and of the ground, the wind, moisture, cloudiness, atmospheric precipitation, and the evaporation of an open mass of water. These observations were made twice a day—at 8 a.m. and 2 p.m. The observations thus obtained were collected at the station of Eberswalde, and published regularly in monthly and yearly reports. From the body of observations made at thirteen stations in operation since 1873, Prof. Müttrich had now made a more special investigation into the influence of the forest on temperature. In order to obtain data to serve as a basis for determining the influence exercised by the forests on the daily march of the temperature, he had caused observations to be instituted in Eberswalde every two hours throughout a period of fourteen days from June 15 to 30. The graphical representation of these observations showed that the curve of temperature for the field station, starting from the point reached at midnight, sank a little at first, then rose at a quick, but later on at a somewhat abated, rate to its maximum at about two o'clock, whence it sank again, rapidly at first, then more slowly, to its midnight level. The curve of temperature for the forest station had, generally speaking, an analogous course. At midnight, however, its curve started at a higher point than that of the field station, crossed the latter at 5 a.m., and afterwards continued to be lower than the field curve, till at 8 p.m. it

intersected the field curve for the second time, and thence continued above it till midnight. The difference in the maxima of the two curves was considerably greater than the difference in their minima, that is to say, the wood exercised during the day a more powerful cooling influence than it exerted a warming influence during the night. The maximum of the forest curve, besides, occurred from half an hour to an hour later than that of the field curve. For the further study of the influence of forests on temperature, the data of the maximum and minimum thermometers were utilised. From these were calculated the daily variations of temperature for the different months at the different stations, and the yearly course of these variations for each particular field and forest station was exhibited by a curve, the abscissæ of which were the months and their ordinates the mean daily oscillations of temperature. From the curves of the various stations, special curves for the open field, the fir, pine, and beech forests were next deduced. The curve for the field station showed that the daily variations in January and February were within narrow limits and pretty similar, that in March the curve rose, then mounted very rapidly in spring and up to its summer maximum, whence in September it dropped very rapidly, abating, however, its rate of fall in October, and then creeping down very slowly through November and December. The curve for the fir forest was, in January and February, not much different from the foregoing in the same months, but the variations were smaller than in the case of the field station. The curve next rose rather more steeply on to the month of May, and after that proceeded more slowly towards its summer maximum, from which it fell, at first quickly and then slowly. All along, however, it kept inferior to the curve of the field station, the interval between the two being much greater in summer than in winter. In the pine forest the curve marking the variations of temperature showed a similar course, except that from January to April it approached much nearer the curve of the field station than did the curve of the fir forest, while in summer, on the other hand, it kept at a greater distance from that of the field station, but joined the fir-forest curve in autumn. Thus the curve of the pine forest likewise all along kept below that of the field station. The difference between them was less in winter, and in summer it was almost just as great as the difference between the field curve and the fir-forest curve. Altogether different, however, was the curve of temperature and its variations in the beech forest. In January and February it lay at but a very little interval below that of the field station, came up almost quite level with it in spring, or even shot just a very little beyond it, attained its maximum for the year in May, whence it at first rather slowly, but afterwards very rapidly, declined. In the beech forest, therefore, after it put on its full foliage in May, the variations of temperature lowered considerably, showing a very wide difference throughout the months of July and August from the variations of temperature obtained for the same period in the open field. The disfoliaged forest, on the other hand, showed hardly any sign of having affected the variations of temperature. The maxima, as also the minima, of temperatures were likewise calculated by the month for the different stations, and from the data thus obtained the annual curve was drawn. For the open field the curves of the maximum and of the minimum temperatures showed a pretty similar course, the maximum of both occurring in summer, and the rise and fall of the curves being likewise tolerably uniform. For the forest station the curves of the maximum and of the minimum temperatures were different. The maximum curve lay, on the whole, lower than the corresponding curve of the open field. It moreover attained its utmost height in May, resting there, with but slight changes, throughout the summer. In autumn the curve sank, reaching, in winter, quantities not essentially different from those of the field curve. The curve of minimum temperatures, on the other hand, in the case of the forest station, showed higher values than obtained in the case of the free station. In the pine forest the course of the minimum curve came nearer to that of the field curve, and there, too, a maximum was found in summer. In the beech forest, however, the curve attained its maximum as early as May, keeping that level pretty nearly all through the summer, but sinking more rapidly in autumn, and descending lower than did the curve of the pine-forest station. As a result of his investigation, Prof. Müttrich had arrived at certain definite conclusions respecting the influence of the forest on temperature, which may be stated as follow:—(1) The forest exercised a positive influence on the temperature of the air; (2) the daily variations of temperature were lessened by the forest, and in summer more than in winter; (3) the influence of the leafy forest was in summer greater than that of the pine forest, while in winter the tempering influence of the pine forest preponderated over that of the disfoliaged forest. An attempt to determining the influence of the forest on the mean annual temperature led to no sure results.

STOCKHOLM

Royal Academy of Sciences, January 14.—Prof. Sven Lovén gave an account of the work done last summer at the zoological station of the Academy, and of the special reports thereon by Dr. Carl Aurivillius on Ostracoda, M. Wirén on Annelida, and M. Fristedt on sponges.—Prof. Lovén also gave the results of his studies on the species of echinoids described by Linnæus, the fundamental specimens of which, formerly in the cabinet of Queen Lovisa Ulrica, exist still in part in the Museum of the Upsala University.—Prof. Nordenskjöld spoke on the inland ice of Greenland, and on the mineral dust found on the same.—Prof. Torell exhibited a geological map of the southern part of Sweden, published by the Geological Survey of Sweden, and also a map of the northern part, delineated at the same institution. He also described other geological maps of Sweden.—Prof. Smitt reviewed the travels of Dr. Emil Riebeck in Asia and Africa, and communicated a paper by the Rev. F. Hammargren on the bleating-like sound of the common snipe.—Prof. Wittrock communicated papers (1) by M. Henning, on his travels in Herjeådalen with regard to its mycology; (2) by M. G. Lagerheim, on his algological researches in the province of Bohus; and (3) by M. C. J. Johansson, on Taphrina, Fr., and the Swedish species of that genus.—The Secretary, Prof. Lindhagen, presented the following papers, viz.:—New or imperfectly known Isopoda described by Dr. C. Borvallius; on the action of the dioxide of hydrogen on earths; on the combinations of samarium; and new researches on the combinations of didymium, all by Prof. P. T. Cleve of Upsala.

A MEDICAL NOVEL.

CHARLEY KINGSTON'S AUNT.

A Study of Medical Life and Experience.

By PEN OLIVER, F.R.C.S. Second Thousand. Crown 8vo, 6s.

"A novel, written by a physician, with a medical student for its hero, would deserve a few words of notice at our hands even if it were of less conspicuous merit than this interesting volume. . . . The plot turns upon a highly dramatic incident, but it is well worked out, and the interest is well sustained until the mystery is fully explained. . . . The scene is laid in one of the best known of our medical schools of London, and old students there will have no difficulty in recognising the truth of several of the portraits which are incidentally sketched. Apart from its technical interest, this book will secure attention by its vigorous writing, its many well-touched pictures of life and character, its clever incidental use of a picturesque and fading rustic dialect, and its side-references and just compliment to some of the social traits of medical character; . . . with touches indicating an intimate knowledge of medical society, and a bright insight into some of the best sides of medical life and character."—*British Medical Journal.*

". . . To every practitioner who wishes to renew the memories of his youth the book may be confidently recommended as the companion of an idle hour."—*Medical Times.*

"'I want to make your flesh creep,' said the Fat Boy to the old lady at Dingley Dell. That is what Mr. Pen Oliver, author of 'Charley Kingston's Aunt,' wants to do to his readers, and does very effectively in his early chapters. But there is much besides 'creepiness' in the book: cheery descriptions of old-fashioned medical-student life, an excellent 'interior' of a common lodging-house, a well-sustained tracking of a mystery, and much of the soft Suffolk talk by one who evidently knows it well. This single-volume story is one which should be asked for at Mudie's."—*The World.*

"Charley Kingston has one of the most startling experiences ever accorded to a medical student. This incident is placed in the foreground of the story where the clever French mystery novelists put the murder. The manner of telling the tale reminds one a little of that of Mr. William Gilbert, who used to write such realistic and powerful stories. This is in our opinion a favourable and flattering criticism."—*Daily News.*

NOW READY, Large Post 8vo, with 15 Maps and 60 Illustrations, Cloth gilt, price 21*s*.

EUROPE,

By F. W. RUDLER, F.G.S., and G. G. CHISHOLM, B.Sc. Edited by SIR ANDREW C. RAMSAY, LL.D., F.R.S. With Ethnological Appendix by Professor A. H. KEANE, M.A.I.

Forming the Concluding Volume of STANFORD'S COMPENDIUM OF GEOGRAPHY AND TRAVEL for General Reading, a Series of Volumes descriptive of the Great Divisions of the Globe.

NOTE.

This volume on "Europe" is based, like the others of the Series, on Hellwald's well-known "Die Erde und ihre Völker;" but it has been found desirable to recast a great part of the original work. The labour necessary being more than Sir A. C. Ramsay could conveniently bestow on it, it was handed to Mr. Rudler and Mr. Chisholm. Sir Andrew, however, corrected the proofs of the entire translation and made extensive additions to the work, adding entire chapters on the subjects in which he was specially interested. By the recasting, the plan of the volume has been rendered much more systematic, and a large portion of the Physical part has been rewritten.

A valuable Essay on European Ethnology and Philology has been contributed, in the shape of an Appendix, by Prof. Keane. Throughout the work great care has been taken to insure accuracy, and to present the latest additions to our knowledge of the various subjects under discussion. Equal care has been taken in the preparation of the series of maps, which will, it is hoped, be found valuable accompaniments to the text.

London: EDWARD STANFORD, 55, Charing Cross, S.W.

G. CALVER has received HIGHEST AWARD for "Excellence and Improvements" in Reflecting Telescopes exhibited at the International Exhibition, London.—Descriptive Catalogues, twelve stamps.

With numerous Illustrations, Crown 8vo, 3*s*. 6*d*.

POLARISATION OF LIGHT. By W. SPOTTISWOODE, LL.D., late President of the Royal Society, &c. New Edition. [*Nature Series*

MACMILLAN & CO., LONDON.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/5 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharin, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for Invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

THE "LOISETTIAN" SCHOOL OF MEMORY.

INSTANTANEOUS MEMORY!
ART of NEVER FORGETTING!!
DISCONTINUITY CURED!!

A Physiological System, wholly unlike Mnemonics, using none of its "Localities," "Keys," "Pegs," "Links," or "Associations."

Dr. ANDREW WILSON, F.R.S.E., Editor of "Health," says:—
"PROFESSOR LOISETTE'S SYSTEM IS PHYSIOLOGICAL AND SCIENTIFIC IN THE HIGHEST DEGREE."

Mr. RICHARD A. PROCTOR, Editor of "Knowledge," in No. 117, dated January 25, 1884, says:—
"I HAVE NO HESITATION IN THOROUGHLY RECOMMENDING THE SYSTEM TO ALL WHO ARE IN EARNEST IN WISHING TO TRAIN THEIR MEMORIES EFFECTIVELY, AND ARE THEREFORE WILLING TO TAKE REASONABLE PAINS TO OBTAIN SO USEFUL A RESULT."

Any Book Mastered in *One Reading*.
Great Inducements to Correspondence Classes.
Prospectus post-free on application to
PROFESSOR LOISETTE,
37, NEW OXFORD STREET (opposite Mudie's Library), LONDON.

BROWNING'S PLATYSCOPIC LENS.

Engraved Real Size.

A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively, 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s.* 6*d. each power.*

Illustrated description sent free.

IRON AND STEEL

Principles of the Manufacture of Iron and Steel. By Lowthian Bell, F.R.S.

THE work before us, as its title indicates, does not attempt to describe the plant or the manipulation involved in the successful conduct of the several processes pursued in the manufacture of iron, but is confined to a scientific discourse upon the reactions and economics of the production of iron, and more especially upon the question of the economical consumption of fuel in the blast furnace, as based upon the author's long practical experience as a Cleveland ironmaster, fortified by the results of, and deductions drawn from, the numerous and carefully-conducted experiments which he has made upon the chemistry and physics of iron-making. These results have been previously largely published at different periods in the *Transactions* of the Iron and Steel Institute; but, as the author says in his introductory chapter, they "were described in the language of the laboratory," and it is his desire in the present volume to present the general results at which he had "arrived in a more consecutive and less attractive form than that necessarily adopted under such circumstances, and to correct any opinion therein stated which further observation had shown to require modification." The book also contains some valuable considerations of a more commercial character than those usually found in scientific or technical works.

After an introductory chapter, Mr. Bell devotes a section to an interesting historical sketch, arranged in chronological order, of the progress and improvements effected in the iron manufacture, commencing with the primitive forge found in the interior of Africa and closing with the introduction of the basic process for the manufacture of steel. Then follows a chapter upon the direct processes for making malleable iron, in which the economic results of these processes, as against the indirect methods (where the blast and puddling furnaces are conjointly employed), are discussed adversely to the direct processes. Mr. Bell considers that, owing to their simplicity and the partially oxidising tendency of the operations of direct smelting, whereby the phosphorus in the ores is largely left in the slags, these processes have received during the past thirty years more attention than they merit. The author's ideal is a well-appointed blast furnace which expels oxygen from the ore, intercepts the escaping heat, and raises the product to the desired temperature in one apparatus. Owing to an erroneous assumption, viz. that the cost for melting steel in the open hearth furnace is the same whether pig iron and iron ore, or pig iron and scrap, are the materials employed, the author is led to compare somewhat unfairly, on p. 39, the cost for fuel and labour of the product of the Siemens rotary furnace with pig iron produced in the blast furnace. The comparison is made as though the two products were the same, whereas the rotator-blooms are used in the open-hearth steel process in lieu of malleable iron, and not as a substitute for "iron in the form of pig," and hence the comparison should fairly be made as between rotator-balls or blooms and balls or blooms of suitable quality as made by the indirect process of puddling the product of the blast furnace.

Section IV. is devoted to a brief consideration of the preliminary treatment of materials for the blast furnace, such as coking, charcoal-burning, and the calcination of ores; and with Section V., at page 61, the author commences his discussion of blast furnace phenomena, which he continues through Sections VI., VII., VIII., IX., X., and XI., devoting altogether a space of 282 pages to this division of the subject; whilst Chapters XII. and XIII., occupying only forty-eight pages, suffice for the discussion of the phenomena and economic results attending the production of malleable iron from pig iron in low hearths, together with considerations upon the action of the refinery, and of the various forms of puddling furnace, from that of Cort to the Danks, and other mechanical puddling appliances.

Section IX. gives much information of a speculative character, bearing upon the causes of the observed alterations in the relative proportion of carbon, oxygen, and nitrogen to each other in the gases withdrawn at different levels below the furnace throat. A like remark applies to the theories propounded to account for the origin and behaviour of cyanogen compounds in the blast furnace, and likewise to the explanations offered for the appearance of bodies, such as silica, lime, alumina, magnesia, oxide of zinc, and oxide of lead in varying relative proportions in the fume withdrawn with the gases taken at different depths in the furnace.

In Section X. the author maintains the conclusions previously arrived at in his "Chemical Phenomena of the Blast Furnace," viz. that in practice, when smelting Cleveland stone in well-appointed and well-managed blast furnaces of 80 feet in height and from 11,000 to 25,000 cubic feet capacity, driven by a blast heated in pipe-stoves to a temperature of from 500° C. to 600° C., that a ton of pig iron can be produced with the consumption of 20·4 cwt. of coke, which the author calculates is within 1·26 cwt. of the minimum consumption of coke required by theory to smelt a ton of pig iron from the ore in question. He maintains that such furnaces are, and must be as economical in fuel as larger furnaces driven by blast heated in brick stoves to a temperature of 800° C.; but he does not directly venture to dispute the advantage of an increased make per 1000 cubic feet of capacity effected by the larger furnaces and the higher temperatures of blast employed in them.

Mr. Bell dismisses, in the sixty pages of Chapter XIV., the consideration of the manufacture of steel by the Bessemer, the dephosphorisation or basic process, the open-hearth processes, known as the Siemens-Martin, and the ore process. The manufacture of steel in the Pernot furnace, by the cementation and the puddling process, are here also discussed, and in the same chapter are also described the reactions and investigations which resulted in the author's purifying or pig-washing for the dephosphorisation of pig iron by means oxide of iron added to the charge of phosphor contained in a rotating furnace. Further, there is XIV. an important sheet of six diagrams, g

representing respectively the order and rate of removal of silicon, phosphorus, and carbon from pig iron in the author's purifying process, in the Bessemer converter, with both acid and basic linings, during the process of mechanical puddling, in the refinery, and during the process of puddling by hand labour.

The thirty-four pages of Section XV. of the volume are devoted to the consideration of facts and figures better calculated to interest the trader and economist, than the manufacturer or scientist; it contains extracts from the statistical returns of the condition of the trade, and make of iron in Great Britain, Germany, France, Belgium, and the United States. Then there follow two sections full of interesting and valuable information upon the labour question, and the effects of free trade principles upon the iron industries. In these sections comparisons are made of the relative cost and efficiency of the British workman as compared with his continental competitor and his American cousin. Commencing with the agricultural labourer, the coal and ironstone miner, the labour employed at the blast furnace, the puddling furnace, in the Bessemer and other methods of steel production, and finally in the engineering and shipbuilding industries, the author shows that throughout, although wages are considerably higher in Great Britain than in any Continental iron-producing district, yet that the English workman, being better fed, does more work per day than his competitor; or, in other words, fewer hands are required in Great Britain than are necessary for the performance of the same work where foreigners are employed. The comparison with the labour of the United States stands, however, differently, the American workman, as a rule (not without exception), receiving a higher rate of wages than the corresponding class in England; such examples being conspicuous amongst the various classes of mechanics, while the individual labourer at the blast furnace is paid at about the same rate in the two countries; but from various causes Mr. Bell states that "the labour on a ton of metal in America amounts to nearly double, and often more than double, its cost in England," and similar results apply to the production of malleable iron by hand-puddling, or to steel ingots from the Bessemer converter.

The last chapter of the volume compares with one another the chief iron-producing countries of the world, their national resources, their competition with Great Britain in English and foreign markets, and the effects of improvements, more especially of the basic process, upon the German steel industries. Mr. Bell concludes the volume with a brief discourse upon the present prospects of the iron trade of the world, and draws the conclusion that the cost of production of pig iron and of steel cannot be materially reduced, except by the reduction of royalties, railway charges, and wages; whilst the puddling furnace is doomed to extinction by its more powerful rivals the Bessemer converter and the open-hearth steel-melting furnace; so that there is little inducement for ironmasters to incur any expense in experiments aiming at the improvement of mechanical puddling appliances. The last-mentioned conclusion is pretty generally accepted, but that the cost of producing pig iron and steel cannot be materially reduced may well be questioned when the immense developments of the last twenty years are considered; and there are many who still hope to see some continuance of this progress, possibly in the direction of a still more economical production of steel from phosphoric and other inferior ores, either by direct processes or by improvements in the existing types of procedure.

The statistical portion of the work is often very indefinite as to the date to which the figures apply to different localities, and the six sections comprised between pp. 61 and 342, treating as they do of the reactions in the blast furnace, the use and theory of the hot-blast, the quantity and quality of fuel required in the blast furnace using air at different temperatures, of the solid products and of the chemical changes as they take place in the blast furnace, on the equivalents of heat evolved by the fuel in the blast furnace, on hydrogen and certain hydrogen compounds in the blast furnace. Each of these sections contains, as might be expected, much valuable information upon the theoretical considerations affecting the combustion of fuel, the effects of increasing the height and capacity of the furnace, and the limits to which the temperature of the blast may be raised with economical results; but the sections might be advantageously condensed, and much repetition avoided, by a more systematic arrangement of the facts and data.

The chemical analyses, results of experiments, the various facts and data, statistical and otherwise, with the discussions thereon as contained in Mr. Bell's volume, make it a most important and invaluable contribution to the literature bearing upon the scientific and economic considerations of our great iron industry, and this notwithstanding that the theoretical deductions which the author propounds may fail to secure universal acceptation.

W. H. G.

PHILLIPS'S "MANUAL OF GEOLOGY"

Manual of Geology, Theoretical and Practical. By John Phillips, LL.D., F.R.S. Edited by R. Etheridge, F.R.S., and H. G. Seeley, F.R.S. Pp. 546. (London: Chas. Griffin and Co., 1885.)

THERE are two ends which a Manual of Geology, or for the matter of that of any science, may be intended to compass. It may be meant for beginners, or it may be designed for the use of advanced students. And the ways in which the subject must be handled in order to meet the needs of the two classes are essentially distinct; for it is no less true in intellectual than in physical development that the infant and the adult require different modes of treatment and different kinds of nourishment.

At the very opening of the work before us we find, on a fly-leaf by itself, evidently placed in a conspicuous position for the purpose of calling special attention to it, the aphorism, "Knowledge should be practical from the first," and directions follow as to the way in which the reader can best obtain the specimens by the aid of which alone his knowledge can be rendered practical. Such instructions would be superfluous in the case of advanced students, and we must conclude that the book is intended for beginners. We are warned in the preface that "of things good and beautiful the gods give nothing to men without great toil"; this is a truth which the real teacher never fails to impress on those whom he aspires to guide along the rugged roads that lead to the heights of learning, but at the same time he finds his first and best joy

in rolling aside as far as he can the obstacles that lie so thick on the path, and, when he cannot clear them away, in helping the novice with tender, loving hand to surmount them, and the wish that lies nearest to his heart is to make the journey as smooth and easy as is compatible with thoroughness. It can scarcely admit of a doubt that the way to do this is to begin with the simple, the known, and the certain, and gradually lead on to the complicated, the doubtful, and the hypothetical. And it is not only because it smooths the beginner's path that this is the more excellent way, it is even more than that, because it engenders from the outset a habit of clearly distinguishing between what we may fairly look upon as established truths and the things which are still matter of speculation. If hypotheses are forced on the student's attention in the early part of his career, and still more if these hypotheses are spoken of as if they were universally-accepted doctrines, the learner soon ceases to distinguish between fact and theory, and his scientific studies lead only to confusion of thought and a habit of jumping to conclusions from imperfect data.

It is for these reasons that I cannot help doubting the wisdom of introducing so early as the second chapter questions about which so very little is known for certain as the composition and condition of the earth's interior, the origin of the earth's figure, and the nebular or meteoric origin of the earth itself. The author is, however, countenanced in this by the practice of many eminent geologists, and I will not therefore press the objection; but I feel little doubt that he has not acted in the best way for the interests of those for whom he seems to have written when, only two chapters further on, he plunges into the vexed question of the origin of the crystalline schists. Chapter IV., which deals with this matter, begins, "The newest water-formed rocks are similar in appearance to deposits which are now being deposited." Not a word has yet been said about the class of rocks described as water-formed, nor any reason given why they are believed to have been formed in water. Why should this be taken for granted when it is a matter so easy to understand and about which there is so little difference of opinion? Surely it would have been safer for a beginner to make the demonstration of a proposition so simple as this his introduction to the study of geology, than to launch him at the outset on a sea of speculation when he is tossed to and fro by conflicting theories and bewildered by the opposite opinions which different authorities hold. Our author, it is true, evades this danger, but he does it in a way that is distinctly unfair to his readers. He shows that it is not impossible that crystalline schists may be produced by the metamorphism of sedimentary deposits, and then lays it down, without any further reason, that *all* rocks of this class have been produced in this way, but he says nothing to lead us to suspect that this is at best an hypothesis, still less that it is an hypothesis which many geologists decline to accept. This looks very much like one of those sweet and easy ways which are so severely denounced in the preface. Nor is his further development of the subject any less unsatisfactory. He gives one of the many reasons that have been alleged in favour of the view that granite is also a product of metamorphism; goes on to the further step that granitic rocks are the deep-seated forms of lavas, and so leads up to the conclusion that all crystalline rocks are metamorphic products. There are many geologists, myself for one, who look favourably on this speculation, who are even sanguine enough to believe that the day will come when it will be placed among established facts, but I could hardly have thought it possible that any scientific writer could have stated it in the present day as a thing about which there was no question; and it scarcely seems prudent, when geology offers us so much that is sure and certain on which to base our teaching, to choose one of the most speculative of its tenets as the foundation for a scheme of instruction.

A chapter follows on the "Nature, Composition, and Origin of the Water-formed Rocks," which illustrates under a typical form the defects and excellences of the greater part of the book. There is much admirable matter and the illustrations are well chosen, but it would be very hard to teach from this chapter. The facts are all strung together in a continuous narrative, somewhat scattered, too, so that if we wished to make out all the steps in the formation of a certain rock, say an organic limestone, we should have to pick out a clause here and a sentence there and piece these fragments together. In fact, this and many other parts of the book remind us of a formation rich in organic remains, but requiring much labour to unravel because the fossils are embedded in rock, are mixed confusedly together, and are, many of them, fragmentary. We do not put a beginner in palæontology to work on such a deposit, but let him first get systematic knowledge in a museum where the fossils have been extracted and set up in order. And it is just such orderly arrangement of the facts and the deductions that follow from them which is wanted in a scientific manual intended for a beginner; they ought not to be embedded in the text, where they have to be hunted for, but they want picking out and placing each by itself in a strong light so that they may catch the eye of the student. Again, if we remember that the materials out of which the water-formed rocks are built up were furnished by denudation, it would seem that an account of the origin of these rocks must necessarily begin with a description of the mode of action and products of denuding agents, but for this we have to wait till we reach Chapter XI. That chapter and Chapter X. furnish one of the most perfect instances of the "cart before the horse" to be met with anywhere. Chapter X. is headed "The General Features of the Scenery in their Relation to Geological Phenomena"; in it, while due weight is given to the influence of upheaval in determining the shape of surface, the large share which denudation has played in forming hill and valley is fully recognised; but it is not till we come to the following chapter that we are told what denudation is and how it works.

The author may say, however, that all this is very much matter of opinion, that I have my notions as to the way in which geology is to be taught and the order in which its subject-matter is to be presented, and that he has his. It may be so, but there are in the book slips and errors about which there can be no difference of opinion, and to which I feel sure the author himself will be glad to have his attention called. We do not generally describe charcoal as uncrystallised diamond, but this would be nearly as bad as "calcite in an uncrystallised condition" (p. 47);

we can hardly agree with the statement that "clay is identical in composition with felspar" (p. 46), when we remember that the one contains about 47 and the other about 65 per cent. of silica; it is somewhat a surprise to find the old time-honoured section of a mountain chain, given in Fig. 34, p. 80, still surviving; if one wished to select a section of what a mountain-chain is not like, here we have it. What would Mr. Huggins say to the statement on p. 17, that "the nebulæ are now known to be in no respect nebulous"? On p. 22 we are told that, "when a typical felspar contains potash, it is recognised by fracturing at right angles to the side (*sic*) of the prism." This is hardly calculated to convey a notion that potash felspar has two cleavages, and certainly gives no definite idea of the direction of either.

The treatment of the subject of joints is bewildering; it reminds me of the advice given to a youthful and diffident teacher, "If you are asked to explain any thing you don't understand, look solemn and talk of polar forces." We have vague hints that the crystallisation of monoclinic augite and triclinic plagioclase may in some mysterious and unexplained way have determined the direction of the cracks on the hexagonal jointing of basalt, and that the structure is essentially crystalline (p. 43); then, on p. 82, our mind is unsettled by the statement that tension in successively different directions is more probably the true cause of the phenomena of jointing in slaty rocks; then heat and electricity, it is surmised, may have had something to do with it. Surely in the place of these guesses, or at least in addition to them, it would have been well to mention some of the facts that throw light on the solution of the problem; that the columnar structure of basalt is closely mimicked by the hexagonal columns of starch and dried clay in the formation of which crystallisation took no share; and that Daubrée has produced, by torsional strain, cracks, the directions of which follow the same law as governs the trend of master-joints in rocks. It is this preference of shadowy surmise to solid substantial fact which constitutes one main fault of the book. The notice of "reversed faults" on p. 77 is incomplete; Rogers and Heim have taught us that these are the rule in violently contorted districts, and the latter has given a beautiful explanation of how they have been produced. The formation of coal is dismissed in ten lines, at least this is the only reference to coal given in the index, and I have not found anything on the subject elsewhere in the book. When I think what an admirable instance of inductive reasoning the discovery of the terrestrial origin of coal supplies, and how the study of sound inferences like this is one of the best ways of developing the logical faculty in the student, I cannot help regretting that some of the questionable speculations with which the book abounds have not been left out to make room for an account of the way in which this truth was arrived at. I fear very much that the directions given on p. 253 will not help the student much to identify minerals under the microscope. One would gather from them that colour was the one important point to attend to, for this is almost the only thing noticed; and it is strange that in the case of olivine, where the extreme vividness of the colours is of some little use as a distinctive test, no notice is taken of the fact. Amphibole, it would seem, is to be distinguished from pyroxene by giving brighter colours, but the widely different cleavages of the two minerals, and the dichroism of the one and its absence in the other are passed over. Nor is a word said about the dichroism of tourmaline and magnesian mica. Of the many points to be attended to only one is mentioned, and the most important facts under that head are omitted.

For such reasons as I have given I cannot help feeling that this work is unsuited for teaching purposes; indeed, on account of the way in which it mixes up theory and fact, I should say it would be positively dangerous to put it into the hands of a beginner.

But it will be by no means without its use to those who have made some progress in the study of geology. It is an admirable geological gazetteer. The long lists of localities where typical examples of the various classes of rocks may be studied and the condensed descriptions of the geological structure and history of the various districts cited, will be of great value. References to original memoirs are frequently given, but they might be largely increased with great advantage; it would be scarcely possible to make them too numerous. There is much, too, in the speculative portion of the book, which, even if it be in places hazy and but slightly supported either by observation or experiment, is still very acceptable. Even the guesses of an acute and original thinker are welcome.

In the section devoted to palæontology the puzzles and uncertainties of that branch of geology are stated without reserve, and the lines on which the palæontologist must work are clearly marked out. The chapter on the "Succession of Life in Classes and Orders of Animals" is too crowded with detail for beginners, but I fancy that the advanced student will often turn to it for reference and thank the author for having furnished him with such a concise index to the subject. The brief indications given under each head will serve as starting points, and as he develops and expands his knowledge by the aid of special treatises and original memoirs, the student will find out for himself where the author is propounding his own peculiar views, and where he is in accord with his fellow-palæontologists.

A. H. GREEN

OUR BOOK SHELF

Transit Tables for 1885. By Latimer Clark, M.I.C.E., &c. (London: E. and F. N. Spon, 1885.)

AT a period when the question of universal time is in every one's thoughts, more or less, these tables should possess more than ordinary interest. By the production of a simple, efficient, and inexpensive transit instrument Mr. Clark first demonstrated that transit observations were within the power of others than the professional astronomer or the wealthy amateur, and that by these observations timekeepers could be regulated to the fraction of a second. The next step was to simplify the calculations involved in the reduction of these observations, by the yearly publication of tables giving in Greenwich mean time, instead of sidereal time, the transits of the sun and a few of the principal stars conveniently situated for observations for every day in the year. This is chiefly what is accomplished in these tables, now in their fourth year of publication. In addition to the fundamental stars, the transits of five of which are given for every

day in the year, there are tables by which the transits of about twenty others can be computed by the simple addition of their R.A. converted into mean time from that of one of the fundamental stars. The transits of the major planets and of certain bright stars suitable for daylight observations are also given, and the tables show the declination and meridian altitude of sun, stars, and planets. There is a monthly ephemeris, and in additional tables will be found the time of sunrise and sunset, daybreak and nightfall, the sidereal time at a certain epoch of mean time (9 p.m.), and the sun's semi-diameter for every alternate day. In the preface are clearly-written instructions for fixing and adjusting the instrument, and for obtaining local or Greenwich time at any place in England or abroad. The times are given to the nearest tenth of a second, and the tables are clearly printed in bold type.

Reise nach der Insel Sachalin in den Jahren 1881-1882. Von J. S. Poljakow. Aus dem Russischen übersetzt von Dr. A. Arzruni. (Berlin: Asher and Co. 1884.)

THE author of this volume is a zoologist who filled for a considerable period the office of Conservator of the Zoological Museum of the Russian Academy of Sciences. He has also travelled widely on scientific missions in outlying parts of the Russian empire, and has already studied a portion of the zoological collections sent home by Col. Prejevalski from his Central Asian journeys. The importance which the large island of Saghalin, off the mouth of the Amour, is believed to possess for Russia, led the Geographical Society of St. Petersburg to despatch Mr. Poljakow to study the island and to report upon it from a scientific and economic point of view. He took passage from Odessa accordingly, in a ship conveying convicts, and arrived at the mouth of the Djuka, in Saghalin, in June, 1881. During the succeeding fourteen months he travelled all over the island, along the water-ways—which are the only ways there—when travelling was possible, and arranged his collections when the weather and the season rendered advance impossible. This volume is composed of the letters addressed to the secretary of the Geographical Society, detailing his movements when travelling. For the most part they are such as the most unscientific traveller might address to a friend: they describe the incidents of his various journeys, the superficial customs of the natives he met, the difficulties of travel, his views of the island as a penal colony, its agricultural and mining prospects, and much else of a general and chatty kind. Here and there in the course of the narrative it is apparent that behind these ordinary incidents of travel there is a scientific purpose, which only comes out casually and by chance. Not that there is any concealment about the work; but the real results of the exploration will probably need more examination and arrangement than he has yet been able to give to them. Towards the end he summarises his work in the island, and the summary is worth giving, as showing us what we may expect from him now that he has time for study and arrangement. His collections on leaving the island were, he tells us, enormous. He possessed all the most important representatives of the mammals, birds, fishes, and amphibia, as well as numerous examples of the lower animal world—insects, crustacea, mollusks, &c. One of the most important places in his collection is occupied by ethnographical and anthropological objects. He has ample material to investigate and characterise the original population of the island, which has now disappeared, viz. that of the Stone Age, as well as the race which dwelt around Patience Bay, and which knew the use of metals. It is highly probable, he thinks, that aborigines who belonged to the Aino stem were so numerous a century and a half or two centuries ago at the mouth of the Poronai River that their settlements on a limited space then contained a larger population than the whole of the island does to-day. The present inhabitants, the Gilyaks and the Orokos, have retained many of the characteristic features of the culture of their predecessors. The present inhabitants of Saghalin, like the former, concentrate all their activity in hunting and fishing, and they seek their sustenance on the land as well as in the seas and rivers. He notices that the natives, and especially those of the southern part of the island, have been largely influenced by the Japanese, who go there in the summer to catch fish, and that this influence has lasted for centuries. It is only a few years since the Russians commenced to settle Saghalin, in order to introduce European agriculture and industry. Their first task was to work the coal-measures and to develop agriculture and stock-raising. But there are great difficulties to be overcome. Coal-mining, Mr. Poljakow thinks, will be successful when the methods are completed, the prices lowered, and the delivery of the coal on board ship rendered easier. The rough and cold climate must always be an obstacle to farming; marshes cover a large part of the island, and the larger rivers are subject to frequent alteration of their beds. In fact, the climate and topography of Saghalin offer no natural advantages that would lead one to prophesy smooth things of its agricultural future. The development of the fisheries would form an undoubted source of income, as salmon and herrings are numerous and can easily find neighbouring markets. "I left the island of Saghalin," concludes Mr. Poljakow, "persuaded that it was possible—nay, advantageous—for the State to cultivate, even if forced labour has to be employed. On the other hand, it was clear to me that the results obtained so far by no means correspond with the means and efforts directed to that object." The absence of a map, however small, to accompany the book is a serious inconvenience.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Gardiner's Researches on the Continuity of Vegetable Protoplasm

DR. JULES SCHAARSCHMIDT, in a paper (NATURE, January 29, p. 290) on "Continuity between the Protoplasmic Contents of Adjacent Cells in Plants," gives what he calls "the history of this subject." But he makes no reference to the elaborate memoir by Mr. Walter Gardiner which I communicated on behalf of that gentleman to the Royal Society. This was read on April 26, 1883, and is published in the third part of the *Philosophical Transactions* for that year.

Dr. Schaarschmidt states in his communication that in 1884 he "claimed the universality of the communication (at least in tissues)." I do not myself feel that the establishment of individual claims to unoccupied territory is as important in the scientific as it appears to be in the political world. Still I think it is only due to Mr. Gardiner to quote in reference to this statement of Dr. Schaarschmidt's, the following passage (the italics are mine) from the conclusion (p. 858) of Mr. Gardiner's memoir:—

"Although I am aware of the danger of rushing to conclusions, I cannot but remark that when these results—which were foreshadowed by Sachs and Hanstein when they discovered the perforation of the sieve-plate—are taken in connection with those of Russow, it appears extremely probable that, not only in the parenchymatous cells of pulvini, in phloem parenchyma, in endosperm cells, and in the prosenchymatous bast-fibres, is

continuity established from cell to cell, but that *the phenomenon is of much wider, if not of universal occurrence.*"

A Plea for the Experimental Investigation of some Geological Problems

THE subject of terrestrial physics involves the study of such a large number of phenomena that it is quite comprehensible that any one investigator must devote himself to only one or two branches of it at the most. The consequence of this is that from time to time some section of this extensive field of research is for a period neglected. Such is really the present state of experimental geology, and especially that branch relating to movements of the earth's surface.

Disturbances perceptible at the terrestrial surface may be looked upon as made up of three very distinct groups: first we have actual upheaval or depression of comparatively large tracts of land. Secondly, we have true earthquakes, which probably are dependent upon a variety of circumstances, as, for instance, the snapping of a rock stratum brought to the limit of its flexibility in consequence of the first group of movements; or the formation and injection of fissures by igneous matter. Lastly, there exists a series of small disturbances imperceptible to our senses and even to ordinary instruments of earthquake measurement, and only discoverable by special delicately constructed apparatus. They seem to be dependent upon a variety of causes, amongst which are those of the two former groups, together with changes dependent upon or in relation with barometric pressure, tidal action, temperature of the air, rainfall, &c.

The upheaval or depression of our earth's surface is the very basis of geological science, for it is in consequence of this that rocks have been brought within the reach of investigation, and that our globe has some dry ground upon which we can live, instead of one continuous expanse of ocean. The changes of level were supposed by the cataclysmic school of geologists to occur suddenly, bringing about entirely new distributions of land and water in a short period of time. Lyell, as the leader of the uniformists, laboured all his life to prove that these upheavals were in the main a slow and gradual process, extending over long periods of time. One of this author's examples which he brought forward in the argument with as much skill and force as an accomplished counsel would have done in pleading a cause, was the renowned (so-called) temple of Serapis at Pozzuoli. This building was for half a century the subject of almost innumerable books and pamphlets, some of which show a vast amount of ingenuity. None perhaps were more elaborately worked out than the volume of researches on the phenomena of this building and the neighbouring coast from Gaeta, around the whole gulf of that name, together with the Gulf of Naples, to the Punta Campanella. The author there brings forward a large amount of genuine evidence to show that during the last 2000 years the whole coast has been in a state of oscillation, so that the relative change of level of the land and sea has been as much as 12 m. So far as Niccolini's investigations were capable of being carried out, abundant evidence showed that about the second or third century B.C. the coast line commenced to descend, and continued to do so gradually until the 10th or 11th centuries, when elevation took place for nearly 6 m., till in the sixteenth century, when depression again set in. This depression is now going on in a remarkably rapid manner. I have in my possession an engraving of the temple of Serapis, in which the base of the three columns stands on the upper antique pavement of the building, which is perfectly dry. This is dated 1810. In Niccolini's work is another drawing, made in 1845, in which water had commenced to collect, so that it was necessary to wade about. In 1879 a layer of earth of over a metre had been spread over the floor to make access convenient, the standing column being surrounded by brickwork cylinders, and standing in water of over a metre in depth. The ground was then dry, but from time to time when I visited the building I found puddles commenced to collect, which at last grew so large and deep that lately an additional layer of sea-sand has been added to further raise the level. Similar variations have been observed in other parts of both of the Mediterranean and Adriatic coasts of Italy, which all seem to indicate that this geologically speaking young peninsula has not yet stopped growing.

But if the coast-lines are altering, are we not justified in supposing that the axial ridges of the Apennines are not doing so also, even in all probability to a far greater extent, though from the want of a fixed datum-line, such as the sea may afford, we are unable to appreciate the amount of disturbance? It is not likely that this change of levels exceeds 50 m. in historic times in Italy.

If we even accept the recent reports from Spain as gross exaggerations, we cannot well believe them to be pure inventions when changes of 400 m. are spoken of, which could hardly be asserted without some foundation of truth.

Now, are we not bound in some way to investigate these phenomena, which involve the very principles of geological science? It is strange, but true, that around the Gulfs of Naples and Gaeta no instrument exists for registering the relative level of the sea, nor do there exist any marks on rocks that are officially looked after. During the earthquake of Ischia of 1883 it is not known whether any disturbance of the sea took place, and we are perfectly ignorant of the rate and other characters of the change of the relative levels of the land and sea.

But putting aside this gradual elevation or subsidence, are we not permitting to slip by one of the most remarkable examples of quick elevation and depression which from the accounts that now reach us are taking place in Spain? Were the reports as to changes of three and four hundred metres true, we should be compelled, to a certain extent, to accept in part the teachings of the cataclysmists.

It seems regrettable that England, which is the mother country of geology, should allow such an opportunity as the Spanish peninsula now presents for the investigation of important terrestrial disturbances to slip by. Even if the earthquakes themselves are not studied, little expense of time or money would be necessary to chronicle at least the principal phenomena now in progress, which the Royal or some other Society might well take up.

H. J. JOHNSTON-LAVIS

Iridescent Clouds

THE letters of Prof. Piazzi-Smyth and Mr. J. Edmund Clark (vol. xxxi. p. 148) on iridescent clouds, while interesting, do not, if I mistake not, record any new phenomena. The descriptions given agree very well with that of a phenomenon which I have observed here several times, and which is described in Herschel's "Meteorology," p. 225. Here the phenomenon is usually seen before the approach of the monsoon, and is looked upon as a sign of its being near at hand. Under these circumstances it can hardly be admitted that they have any connection with the cloud glows of which so much have been written, and which, as observed from the top of Doddabetta (8600 feet), are as brilliant as ever when the atmosphere is sufficiently dry.

It may perhaps still be of interest to some to know that observations made on the spectrum of the sun when seen through mists from the same hill-top, showed that the spectrum of the "green sun" can be completely reproduced by superposing the spectra of sunlight passing through a mist and through a thick layer of moist air; and it is probable that all cases in which the sun has been seen green can be thus explained.

Science Teaching in Schools

IN the discussion as to the teaching of science I have failed to find any distinct expression of an element in the subject which has for years seemed to me of the highest importance, and to which I should like with your permission to call attention. In those of our schools where science *is* taught it is almost always taken up late in the boy's career, often when he is passing from the lower to the upper school. This I feel sure is a mistake. Think for a moment of the process of evolution of that phenomenon—the English schoolboy. In too many cases he passes through the first, second, and third forms of a school, learning little more than the habit of diligent plodding, and developing little more than the art of storing away an unheard-of quantity of dry facts. He learns, for instance, page after page of grammar rules; he learns rules for making numerical transformations; he even learns in the same fashion answers to questions that examiners are known to set for the purpose of finding out whether the pupil has been *usefully* taught? The habits so acquired are valuable, but they are acquired at the risk of sacrificing the boy's freshness, and with the subjugation of his habit of independent reasoning. After several years of such training the herald of science comes forward with such a

of. Armstrong very properly suggests. The
ple of science is thunderstruck (as probably not a
f science were when they first saw the scheme),
r of the situation, the sight of new appliances and
, enable him to pull himself together, and his
ime keeps up. Presently he is asked to conduct
ne simple steps of deductive reasoning; he fails,
ness is a new world to him, and in the misery of
ss to do something, he beseechingly asks for
s to devour. What is the ultimate result? If
e taught effectually *it must begin with the earliest
discriminal career*, and there is surely no subject
elf more appropriately to the youthful mind,
ght to talk of flowers, of insects, of the wonders
y are ever asking suggestive questions; they are
collectors of objects of beauty; the Kindergarten
knowledged that the child is an orderly being
ymmetry and colour. Yet we increase his vocabu-
rd "star" and fail to tell him anything of the
rdom. Why, our very fairy tales are based on
ic! To effect this early introduction of science
and most considerate teaching is required, as
a much more difficult task to guide the young
ghts than to guide the veteran student's reading.
ther, a well thought out progressive scheme of
science which shall be suggestive to the teacher
to be pursued. To draw up such a scheme is, I
e, not a matter of moments: it would require the
many minds and many sympathies.
in this direction has been done in France, and
ks are to be found in the English science primers
bert's Book of General Science for the Young;
owever, are not an immediate want—for the matter
pil may make his own—we do, however, want that
lp the conscientious teacher to see how he may
hing of science interesting, intelligent, and above
e. We cannot afford to wait for unintelligent
a natural death, remembering that there is in
iterion that the teacher in the middle-class school
teaching does not pay in examinations, that the
bod lends itself most readily to school discipline,
at the subjects chiefly taught are of such a nature as
clude any other method with the young. Under
ience science is not a growth, it is a graft, and a
e feared, of a most unfortunate nature: the sooner
ots of its own the better. It is, under the circum-
ause for wonder that the more advanced student
common general principles. I have confined my
he sake of definiteness, to middle-class schools, but
lieve, with unessential variation, applicable to the
on of the teaching of science. G. H. BAILEY

Barrenness of the Pampas

as to add a few further remarks on this interesting
as during its investigation that I was so deeply
li the desperate struggle for existence which charac-
ordering fertile zones. I could there watch the
e very battle-field itself, and for that purpose I
yself for some months in the north of Uruguay,
other habitation, among the wooded banks and
e River Arapey. This river, though normally a
is subject to tropical floods, during which the
en thirty feet in eight hours. The "monte," or
l belt on each side, is intersected with ravines and
ng with animal and vegetable life of singular in-
lligator, carpincho, myopotamus, nutria and other
as snakes thrive in the marshy swamps, while in
most with the puma, the jaguar, the great lizard,
, the *Nanas torquata*, and numerous other singular
birds described in my little book. But it was
ss that the principle of natural selection was most
displayed. In such a district, overrun with rodents
cattle, subject to floods that carried away whole
any, and especially to droughts that dried up the
most the river itself, no ordinary plant could live,
ch and watered alluvial *debris*. The only plants
the cattle were such as were either poisonous, or
nuous, or indestructibly tough. Hence we had
evelopment of solanums, talas, acacias, euphorbias,
and laurels. The buttercup is replaced by the little poisonous yellow oxalis with its viviparous buds, the passion-flowers, asclepiads, bignonias, convolvuluses, and climbing leguminous plants escape both floods and cattle by climbing the highest trees and towering over head in floods of bloom. The ground-plants are the portulacas, turneras, and œnotheras, bitter and ephemeral on the arid rock, and almost independent of any other moisture than the heavy dews. The pontederias, alismas, and plantago, with grasses and sedges, derive protection from the deep and brilliant pools; and though at first sight the "monte" doubtless impresses the traveller as a scene of the wildest confusion and ruin, yet, on closer examination, we found it far more remarkable as a manifestation of harmony and law and a striking example of the marvellous power which plants, like animals, possess of adapting themselves to the local peculiarities of their habitat, whether in the fertile shades of the luxurious "monte" or on the arid, parched-up plains of the treeless Pampas. EDWIN CLARK

Great Marlow

Recent Earthquakes

WITH reference to the statement in NATURE, vol. xxxi. p. 262, that the earthquake of December 25, 1884, was registered by the magnetic variation instruments in London, permit me to inform you that an effect was also noticed on a curve of the magnetograph at the Imperial Marine Observatory, Wilhelmshaven. But while at London declination and bifilar were specially affected, here only the Lloyd's magnetic balance, the instrument for vertical intensity, was set in oscillation, first at 9h. 52m. p.m. local time. Full details will be published in the *Zeitschrift* of German Meteorology. Dr. M. ESCHENHAGEN

Wilhelmshaven, February 6

MR. W. A. SANFORD, in NATURE of January 29, p. 289, says on the above subject:—"It would be interesting to know whether anything of the same kind [as described in his letter] had been observed elsewhere at the same time." I have been collecting observations on this subject for a continuation of my paper on earthquakes in Devon, published in the *Transactions* of the Devonshire Association. The Vicar of Bampton has very kindly given me his experience of the earthquake, as the wave appeared to have passed very near, if not directly under, his house. Bampton is seven miles north of Tiverton, and about a mile inside the junction of the Carboniferous and the Devonian systems, situate on a rather large patch of limestone. The time the earthquake occurred there was 8.42 p.m. In the drawing-room at the vicarage it appeared as if a heavy traction-engine was passing close to the window; the window faces eastward. In the kitchen the servants were greatly alarmed by a rumbling noise and a shaking under the floor. Some of the Vicar's neighbours say they heard a report, and houses with cellars under them and higher felt the shaking more; some persons who were up stairs, thinking that it was some explosion, rushed down stairs and out of doors. The effects were also felt at Shillingford, two miles distant, and also at Combehead, one and a half mile distant. The porters at the station describe it as like a heavily-laden mineral train passing. The only damage done at Bampton was a piece of wall was thrown down. This was undoubtedly the same shock or seismic wave as mentioned by Mr. Sanford as occurring on the night of Thursday, January 22, and would appear to have travelled from east to west.

CIVILISATION AND EYESIGHT

IN his interesting paper on "The Influence of Civilisation upon Eyesight," read recently before the Society of Arts, Mr. Brudenell Carter supports the commonly received view that the vision of savages is far more acute than that of civilized men. In some sense this is doubtless true; but that the eyes of savages, considered merely as optical instruments, are greatly superior to our own appears to be inconsistent with optical laws and facts long since established by the labours of Airy, Helmholtz, and other investigators. It is known to physicists that the resolving power of an optical instrument is limited by its *aperture*. With a given aperture no perfection of execution will carry the power to resolve double stars, or stripes alternately dark and bright, beyond a certain point, calculable by the laws of optics from the wave-length of light. With sufficient approximation we may say that a double star cannot be fairly resolved unless its components subtend an angle exceeding that subtended by the wave-length of light at a distance equal to the aperture. If we take the aperture of the eye as 1 5th inch, and the wave-length of light as 1-40,000th inch, this angle is found to be about 2 minutes; and we are forced to the conclusion that there is no room for the eye of the savage to be much superior in resolving power to those of civilised physicists, whose powers approach at no great distance the theoretical limit as determined by the aperture.

It has always appeared to me that the superiority of the savage is a question of attention and practice in the *interpretation* of minute indications, and that it is comparable with the acuteness of the blind in drawing conclusions from slender acoustical premises. It would be an interesting subject for investigation, but I should not expect to find that when put to a direct test blind people were able to hear sounds wholly inaudible to others.

The increasing prevalence of short sight is a very important matter, worthy of all attention. There is one fact in connection with it which I avail myself of this opportunity of mentioning, in the hope of inducing scientific oculists to give it further examination. I find that, though not at all short-sighted under ordinary circumstances, I become decidedly so in a nearly dark room, seeing much better with spectacles of 36 inches negative focus. In a moderately good light I see rather better without the glasses than with them. From the few observations that I have made I have reason to believe that this peculiarity of vision is not uncommon. With the aid of a set of concave glasses it is easy to try the experiment in a room lighted with gas. The flame should be gradually turned lower and lower, so as to give full time for the pupil to dilate, and for the eye to acquire its maximum sensitiveness. In my own case the most marked indication of better definition is the augmentation of binocular relief.

RAYLEIGH

THE INTERNATIONAL INVENTIONS EXHIBITION

THERE seems now little reason to doubt of the success of the South Kensington Exhibition of next summer—success, that is, from an educational and scientific point of view. What its financial result may be depends upon a variety of circumstances, and perhaps, since it is very improbable that there can be any serious deficit, while, if there is a large surplus, its disposal will, as usual, form a problem difficult of solution, this part of the question does not really very much matter. That Londoners will have a pleasant outdoor lounging place, that there will be abundance of music, that the fountains will be as pretty as last year and the gardens prettier, all this may be taken for granted; but there now seems every reasonable expectation that we shall have more than this, and that the Exhibition will be what it professes to be—a complete illustration of the progress made in the application of science to industry during the past twenty years. At all events if it is not it will be the fault of the promoters, since they have had so large a range of choice that it has only been possible to find space for some third of the applicants, and an enormous number of exhibits have been rejected, not because they were unsuitable or uninteresting, but simply because, when there was not room for all, some must of necessity be excluded.

To begin with, it was thought best to exclude, not only the actual articles which were shown last year, but inventions of the same class, and consequently there will be found at South Kensington this year few, if any, exhibits relating to food, clothing, or sanitation. It appears that this rule has given rise to a certain amount of heart-burning, since reference is found to all these heads in the official classification; but it must be remembered that the announcement was duly made at the beginning that the space to be allotted to these and certain other classes would be strictly limited, and then again it was impossible to foresee how large would be the response to the invitations issued. The task of selection has been a difficult, and indeed an invidious, one; but we think it will be found, when the show is opened in May next, that this thankless task has been performed with great judgment, and with a just consideration of the claims of exhibitors on the one hand, and the interest of the public on the other.

We are glad to have heard that in none of the thirty-one groups into which the inventions' half (we are not now considering the musical part) of the Exhibition is divided, have the applications been deficient; in some they are naturally better than others, but in every one there is enough to provide a fair representation of the condition of its particular industry, and of the improvements which have been made in it during the limits of time with which the Exhibition is concerned. Even this will doubtless be a cause of complaint to those who believe that injury will be done to our manufacturers by the opportunity given to foreigners of imitating our wares and the methods by which they are produced. This is a specious but a somewhat narrow-minded notion; the early history of invention is full of stories of the efforts of inventors to keep their inventions secret, and the constant failure of such efforts may be taken as one of the principal causes which produced the modern Patent system, under which an inventor is protected, so far as law can protect him, in the enjoyment of the property he has created. There are, of course, many instances of processes worked, and successfully worked, in secret; but these are the exception, and on the whole it is found that inventors individually, and industry generally, gain far more by a system of publicity than by one of concealment. So it is with exhibitions. It may be taken as tolerably certain that manufacturers who have any special process which they desire to keep to themselves will not select that particular process for exhibition, and that on the whole manufacturers find exhibitions profitable or they would not be so anxious to engage in them. The suggestion that was made by some wiseacre that the Exhibition should be confined to untried inventions, so that manufacturers (who of course have no other means of hearing of novelties in their own trades) might have the benefit of seeing them, does not, perhaps, call for serious refutation. If the curious collection of rubbish which fills the big building at Washington, devoted to the United States Patent Office, were carted across the Atlantic, and placed in the Kensington Galleries, it is a question whether the public would be more bored, or the manufacturers less instructed.

As would naturally be expected, in an exhibition of this character, machinery will occupy a far larger proportion of the space than on previous occasions; we understand that it has therefore been necessary to make considerable additions to the motive power provided for the

use of exhibitors. Besides the engine which supplied power in the machinery gallery last year, an engine is being erected in the new gallery which is being put up along the north side of the old South Gallery, as described in the *Journal* of the Society of Arts for January 30. A third engine will also be provided, which will drive machinery in one of the Foreign Courts. It will thus be seen that those visitors who have mechanical tastes will be amply provided for.

As regards the prospects of applied chemistry, we are not able to speak so confidently. Probably the completeness of this portion of the show will almost entirely depend on the success of the efforts which are being made by the Society of Chemical Industry to secure a collective exhibit. The announcement made by the executive at the outset, that it was desired to show processes rather than products, is believed to have kept back many manufacturers from seeking to show specimens, while it is obvious that but few chemical processes could conveniently be carried on in an exhibition gallery. Possibly this rule might have been abrogated as regards the chemical section, and we believe that no attempt will be made to enforce it with reference to the collection of the Society of Chemical Industry, in which it is proposed that the information required shall be given by means of a collection of pictorial diagrams, exemplifying some of the more interesting or more important chemical operations.

As our readers are aware, a similar work is being undertaken by the Physical Society in the class devoted to "Philosophical Instruments and Apparatus," though in this case there will be less left for the society to do, since the principal makers of apparatus have come forward in sufficient numbers to ensure a good representative collection. The object, however, of the Society in exhibiting has been not so much to supply deficiencies, as to show the work which has been done by its own members. We believe that the Kew Observatory and the Meteorological Society will also be among the exhibitors, the latter in their old place in the grounds. Besides this, a very interesting exhibit is promised—namely, a fully fitted observatory, which we understand one of our best known makers had offered to fit up.

In the class devoted to Photography, which comes next both in the classification and in actual position in the galleries to the philosophical instruments, the Photographic Society has undertaken to form a collection of apparatus and specimens not likely to be shown by makers. It appears that the Society intend to go a little beyond the precise limits of the Exhibition, and to show a collection of examples illustrating the entire progress of photography from the inventions of Niepce and Daguerre, and it may doubtless be assumed that in so special a case no objection will be raised, especially as but a very small space indeed, and that only on the walls, will be required for what cannot fail to prove a most instructive and interesting collection.

The progress which has been made in electric lighting has indeed been sufficiently illustrated in the exhibitions of last and of the preceding year; in fact, the Health Exhibition offered almost the only public example of any progress at all in England. Doubtless the lesson will be repeated this year, and on a more extended scale, for we learn that considerable additions are being made to the arrangements for electric lighting of the buildings, while it is intended to use the light also for the garden illuminations, an improvement due to the energy of Sir Francis Bolton. If this idea is carried out on the plan which we understand is intended, the instantaneous lighting up of the myriad incandescent lamps by which the gardens are to be illuminated will certainly be one of the most popular, and one of the most wonderful, sights in London next summer.

The above remarks refer only to the English portion of the Exhibition. How much will be contributed by foreign countries it is not yet possible to ascertain. Thanks doubtless to the efforts which were made by certain of the members of the British Association who were in the States last year, the American Court promises to be well filled, and it must be admitted that in the present Exhibition, if we get American ingenuity well represented, we shall not very greatly miss the contributions of other countries, though we hope, all the same, that these will not be lacking.

THE RETINA OF INSECTS

IT might have been thought impossible for any one who has studied the eyes of Arthropods to doubt that the so-called retinulæ are really the nerve-end cells of the eye, and correspond with the rods and cones of the vertebrate eye. The evidence in favour of this view accumulated by the researches of almost every observer, including such eminent authorities as Johannes Müller, Leydig, and Grenacher is so overwhelming that of late years no one has thought fit to dispute it.

Mr. Lowne has, however, at last attempted to overthrow this theory, and in a paper just published in the *Transactions* of the Linnean Society, vol. ii. part ii., on "The Compound Vision and the Morphology of the Eye in Insects," has brought forward certain statements to prove that all the parts of the eye in front of the basilar membrane are dioptric, whilst the true (?) retina is situated behind it.

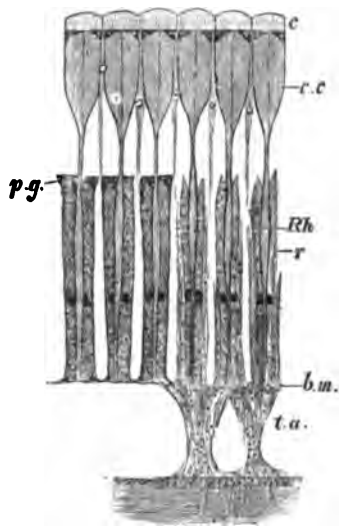

Fig 1.

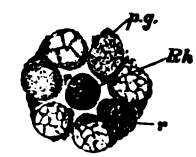

Fig 2.

FIG. 1.—Section through the eye of Squilla, showing the distribution of the ultimate nerve fibrils to the retinulæ. The Ommatidia to the left of the figure are drawn with their accompanying pigment cells (*p.g*) complete; in the three to the right these are omitted in order to show more clearly the distribution of the nerve fibrils; *c*, corneal facets; *c.c*, crystalline cone: *rh*, rhabdom; *r*, retinula; *b m*, basilar membrane; *t.a*, terminal anastomosis of optic nerve fibrils supplying the retinulæ.

FIG. 2.—Transverse section through the ommatidium of Squilla, showing the seven retinula cells surrounding the central rhabdom. The retinulæ are seen to possess a considerable amount of granular pigment, which is unevenly distributed in the different cells.

To one who has been devoting considerable time and attention to the eye of Arthropoda, this proposition is particularly striking and unexpected, and many points at once occur which show that it is untenable.

In the first place it is untenable because we have ample evidence to show that the original theory is the true one. The nerve-end cells throughout the animal kingdom have certain definite characteristics. They are the cells in which the ultimate fibrils of the optic nerve terminate, and no nerve fibrils have ever been seen to leave them to supply other parts of the eye; and, in the second place,

they are always pigmented either by a diffuse fluid "retinal purple," or by pigment in granules, or both.

In both these particulars the retinulæ of Arthropoda resemble the nerve-end cells of other animals.

It is hardly necessary to point out that Leydig, Max Schultz, Grenacher, and many others, have traced the optic nerve fibrils to the retinulæ. I have in my possession several series of preparations showing this both in insects and Crustacea, and any one can readily see this for himself by making even clumsy sections through the eye of Squilla.

In Fig. 1 I have figured the nerve fibrils of the eye of Squilla perforating the basement membrane and entering the retinulæ, and in Fig. 2 a transverse section through the rhabdom and retinulæ showing their relat ve position and numbers.

A special feature of the retinula is that it is always pigmented. In specimens hardened in spirit a granular pigment may be seen in the retinula cells, which is usually of a light-brownish colour and very unevenly distributed (Fig. 2). But in addition to this granular pigment, the retinulæ contain a true retina purple, which fades upon exposure to the light. This was discovered in 1864 by Leydig[1] in the following genera of Insecta:—Procrustes, Scarabæus, and Pieris, and in Astacus among the Crustacea. I have also seen it in *Musca vomitoria*, and have now no doubt that it exists in the Arthropod eye generally.

So far, then, I think it must be admitted that both anatomical and physiological considerations tend to prove that the retinula is the nerve-end cell of the Arthropod eye.

When we turn to morphology, too, we have confirmatory evidence that this is the case.

In the ocellus of the water-beetle larva the retina is a simple cup of pigmented hypodermis cells, in which the optic nerve fibrils may be readily seen to terminate. These cells are most certainly homologous with the retinula cells of the so-called "compound" Arthropod eye, as has been already shown by Grenacher in his important treatise, "Untersuchungen über das Sehorgan der Arthropoden" and elsewhere, and confirmed by the more recent researches of Lankester and Bourne upon the eyes of Limulus and the scorpions.

The researches of Claparède and Weismann on the development of the eye of Arthropods confirms the deductions of morphology, by proving that the cells which ultimately form the retinulæ are specially modified hypodermis cells, and at an early stage come into connection with optic nerve fibrils. If any further evidence were required to confirm this homology it can be readily obtained by studying the eyes of very young cockroaches, in which the retinulæ at the periphery of the eye are formed from specially modified and deeply pigmented hypodermis cells.

But it is tedious and unnecessary bringing evidence of this kind to confirm a theory which is already fully established in the minds of most naturalists. In fact we have here an instance in which morphology, physiology, comparative anatomy, and development combine to establish an homology, and consequently we must definitely assert that the retinulæ are the nerve-end cells throughout the Arthropoda. But what is the meaning of Lowne's bacillar layer behind the basilar membrane? and does it exist in all Arthropods?

It is perfectly true that behind the basilar in many Diptera, Coleoptera, Lepidoptera, and Hymenoptera there is a layer composed of a number of small cylindrical masses which has a superficial resemblance to the rods of the Vertebrate eye, but Mr. Lowne did not *discover* this layer in any sense of the word, for it was perfectly well known to Leydig, who figured it in *Formica rufa*, *Dytiscus marginalis*, and *Sphinx ligustri* (*vide* Leydig's Tafeln, viii. ix. x.). The little cylindrical masses cannot be regarded as cells, nor rods, nor bacilli, for each one of them is composed of a very fine reticulum of nerve fibrillæ which is in direct communication with the optic nerve fibrils behind, and the terminal anastomosis of the optic nerve fibres in front. In fact, these "bacilli" of Lowne are connected with nerve fibrils on both sides, and thus differ from "nerve-end cells" in one of their two fundamental characters.

Very often, too, this layer is quite devoid of any pigment (Apis, Eristalis, Bombyx, Squilla, &c.), and no one has ever yet been able to demonstrate the presence of retina purple in this region.

Another important difficulty in the way of accepting this theory, too, is the fact that this layer is not always present (Periplaneta, Nepa), and in all Crustacea and many insects it cannot be divided into separate bacilli.

I have lately paid considerable attention to this part of the optic tract, but must defer a fuller explanation of the meaning of it until I am able to publish my paper in the *Quarterly Journal of Microscopical Science*, when I shall be able to illustrate my researches by several figures. To summarise, however, the evidence against this layer being composed of nerve-end cells: We find that it is certainly not homologous with the retina of other animals; optic nerve fibrils both enter and leave it; it is devoid of retina purple or of any other form of pigment in many Arthropods, and finally it is absent as a bacillar layer in many insects and in all Crustacea. In fact we can bring as much evidence to prove that this is not the retina as we can to prove that the retinulæ are the true nerve-end cells.

At the conclusion of his paper Mr. Lowne says, in referring to a recent memoir of Justus Carrière of Strassburg, "He remains, however, a disciple of established views, and has not given the retinal layer nearly so much attention as it deserves." I have given the retinal layer as "much attention as it deserves," and must also claim to remain a "disciple of *established* views."

RORAIMA

A TELEGRAM has been received at Kew giving the welcome news that Mr. Everard F. im Thurn has at last ascended Roraima. This has been the cherished object of botanical exploration in South America for the last quarter of a century. The expenses of Mr. im Thurn's expedition have been borne in equal shares by the Government grant of the Royal Society and the Royal Geographical Society.

The latest news from Mr. im Thurn was in a letter dated December 6 from the south side of the mountain, and the following passage describes the position immediately before the final attack:—

"Before we came to Roraima itself we had four days walking through a purely savannah, but most glorious country, and over splendid mountain passes, guided by an Arecuna who said, villain that he is, that he knew the way to Roraima. But at a village marked on the map as Ipelemonta, on the Arnopa River, and with a considerable mountain pass still between us and Roraima, our villain guide at last admitted that the road for some distance had been quite new to him, and that he now knew not how to proceed further. However, at last we procured a guide, and came, in some four hours, out of our difficulties at Ipelemonta (its real name, by the way, is Tooarkring), into this inconceivably magnificent valley, and are installed in a village on the actual southern slopes of Roraima itself.

Yesterday Perkins and I ascended the slope of Roraima to a height of 5600 feet to a most beautiful spot—a very garden of orchids and most beautiful and strange plants. To-morrow, after despatching the bearer of this scrawl, we

me place with a lot of Arecoonas, who are ouse, in which we intend to stop for a week onger as we may find desirable. I may we have already seen, close to where our be, a place where the mountain *seems* t it looks so easy that I am convinced that e at that point."

M. M. P. M.

MASAI LAND[1]

MR. THOMSON has not kept us waiting long for the story of his journey through a region of Africa which, so far as is known, had not previously been visited by any white man. Kilimanjaro itself was seen for the first time by Rebmann. After him Krapf, New, Von der Decken, Hildebrandt, and Wakefield, penetrated to the borders of the region which has been explored by Mr. Thomson, New alone being able to reach the snow-line on Kilimanjaro. Kenia, though doubtfully sighted by Krapf from afar, had never been approached. Mr. Thomson had thus a virgin field before him when he arrived at Zanzibar in the beginning of 1883, and the enterprise intrusted to him by the Royal Geographical Society he carried out in a manner and with results that will add much to the reputation which he achieved on his first expedition to Tanganyika. Mr. Thomson's instructions were to ascertain if a practicable direct route for European travellers exists through the Masai country from any one of the East African ports to Victoria Nyanza, and to examine Mount Kenia; to gather data for constructing as complete a map as possible in a preliminary survey; and to make all practicable observations regarding the meteorology, geology, natural history, and ethnology of the regions traversed. These objects Mr. Thomson never lost sight of, and, considering the means at his command, the time at his disposal, and the blackguardly crew he had to be content with as followers, are even more than might have been expected. Mr. Thomson is first of all a geologist, and no region in Africa is of more interest from a geological standpoint. He knows, moreover, enough of natural history to enable him to observe the flora and fauna of a country intelligently, and the value of his botanical collections has already been pointed out in our pages by Sir Joseph Hooker. For geographical observations he was even better fitted than in his previous expedition, and as for ethnology he found himself among a people unlike anything he had ever heard of in Africa, and in whom he took the intensest interest. Thus for the scientific reader the volume abounds with interest, and, as Mr. Thomson has no end of hunting and other stories of adventure to tell, his book is sure to be popular, especially as he is a skilful story-teller, abounding with a strong feeling of humour, or at least for the ludicrous, which does not spare even himself.

Mr. Thomson's route lay westwards from Mombassa to Kilimanjaro, which he traversed on nearly every side. Here he stayed for some time, ascending a considerable distance towards the Kimawenzi summit. For this magnificent mountain is really double-peaked, the highest summit, Kibo, reaching a height of over 18,610 feet, and Kimawenzi only about 2000 feet lower. The scenic features of the mountain were described in some detail in our columns recently in the paper read by Mr. Johnston at the Geographical Society, in which also its botanical and zoological characteristics were well brought out. Kilimanjaro, Mr. Thomson tells us, may be described as a great irregular, pear-shaped mass, with its major axis in a line running north-west and south-east, the tapering point running into the heart of the Masai country. On this line it is nearly sixty miles long. Its minor axis, running at right angles, reaches only to some thirty miles. The mountain is divided into the great central mass of Kibo and the lower conical peak of Kimawenzi. Towards Kibo the north-west it shades away into a long ridge, which the north-west it shades away into a long ridge, which gradually tapers horizontally and vertically till it becomes

[1] "Through Masai Land: a Journey of Exploration among the Snowclad Volcanic Mountains and Strange Tribes of Eastern Equatorial Africa." By Joseph Thomson, F.R.G.S. (London: Sampson Low and Co., 1885.)

merged in the Masai plain. As to the geological story of the mountain, Mr. Thomson works it out thus :—

"Let me try to trace the sequence of events which have produced Kilimanjaro. An examination tells us that in the serrated peak and rugged sides of Kimawenzi we see the original volcano, which, without doubt, existed long before there was a trace of its neighbour Kibo. Kimawenzi, after the imprisoned earth-forces found vent, rose in size and grandeur, added layer after layer to its height and circumference by a continual alternation of lava sheets and beds of agglomerate and tuff. It appears probable that it welled or belched out its contents without any of those terrific outbursts by which whole mountains are blown into the air or enormous areas submerged under a molten flood; for, curiously enough, we find no evidence that any of its lava-flows ever extended beyond the base of the mountain, or ashes accumulated to any depth in the surrounding country. At the present day the metamorphic rocks are seen to crop out at its very base on the east and south-east, and we have no reason to suppose that they ever were covered by lava rocks. As this—for a volcano—gentle accumulation went on, the hypogene agents would have more and difficulty in forcing the lava up the now elongated vent or orifice, and a time would come when the weight of the column would, in the end, balance the strength of the forces below. We can now imagine the terrible struggle that would ensue as the pent-up gases laboured mightily to relieve the pressure. Doubtless for a time they would succeed occasionally in clearing off the incubus and getting temporary outlet. At last even that would fail, and the volcano was doomed either to become extinct or find another vent. After some grand convulsions the latter was effected, and a new volcano began its existence to

FIG. 1.—Mount Kenia from the West.

the west of Kimawenzi. In process of time it soon rivalled its neighbour in size, and finally towered above it, battering Kimawenzi's hoary head—probably then snow-capped—with showers of stones, and even threatening to obliterate it under the volcanic ejections. Meanwhile Kimawenzi, now no longer under a reign of fire, with its volcanic life-work finished, began, like all things earthly, to crumble away before the slow-boring influence of apparently puny agents. Rain, snow, and frost worked on insidiously but steadily, and soon told their usual tale of denudation as they gradually loosened and washed away the loose ashes which formed the crater, undermined the more compact lavas, and hurled them to the bottom of the mountain; until finally the solid core which had originally choked the orifice stood out a shattered, weather-beaten pinnacle with only a slight indentation to mark the line of the original crater. The beautiful concave curve, so characteristic of large volcanoes, is still to be seen from the east, and speaks of the once handsome proportions of Kimawenzi.

"The fate which befell Kimawenzi soon came upon Kibo. A height was reached which baffled all the attempts of Vulcan to raise the lava to the surface, and, like the other, it became extinct. Evidently, however, the imprisoned forces had either spent their original strength, or they frittered away their terrible energies in the production of numerous parasitic or secondary cones, instead of uniting in another grand effort and producing a third great volcano.

"These cones were spread in great numbers all along the southern side of Kibo and Kimawenzi, and set themselves to the task of strengthening or buttressing them up. An enormous mass of lavas and agglomerates was belched forth, resulting eventually in the formation of what I have called the Chaga terrace or platform, and the long ridge which penetrates far into the Masai country.

estations of volcanic energy were continued
, geologically speaking, are recent times, and
s may view the small cones in many instances
preserved as when they were at work.
t interesting relic of the reign of fire is pre-
e beautiful crater lake of Chala, which lies
nce to the east of the base of Kimawenzi,
few miles north of Taveta. It represents
e latest manifestation of energy, extending indeed into historical times, as the natives have a tradition that at one time a great Masai village stood on its site and was blown into the air, and they will now tell you that at times you may still hear from its liquid depths the lowing of cattle and the bleating of sheep, as well as other village sounds. The shape of the lake is that of an irregular polygon, about two miles in diameter and little short of six miles in circumference. It occupies the centre of a small hill with very irregular rim, 400 feet

FIG. 2.—Lava Cap, Elgeyu Escarpment.

astern plain at its lowest point, and quite 800
st, where it runs up into a peak. The outer

all around at the same angle as the hill itself.
he lake is bounded by perfectly perpendicular
ut a break at any point, at least as far as I
yer, though the natives of Taveta say there is
re the descent can be made: indeed, its dis-coverer, New, declares that he reached the water, and drank of it. I went all around it, and though I am not deficient in enterprise or nerve, I saw no place where I dare descend, not even though I could have swung from creeper to creeper like a monkey."

From Kilimanjaro Mr. Thomson proceeded in a northerly direction, through the heart of the Masai country, to Lake Baringo, making a detour eastwards to

FIG. 3.—Glen of the Guaso Kamuyé.

nia, which in some respects is even more inte-
an Kilimanjaro. From Lake Baringo he pro-
far westwards as the north-east shore of
yanza, not many miles from the outlet of the
north to some strange artificial caves on the
of Mount Elgon or Ligonyi (14,000 feet), and
Chibcharagnani (12,000 feet), back to Baringo,
rth-eastwards to the coast, following a more northerly route after passing Lake Naivasha, which is just about half-way between Kilimanjaro and Lake Baringo. Of course this excellent piece of work was not accomplished without many trials and sufferings. The fierce and warlike Masai threatened many a time to eat Mr. Thomson and his men up, and it was only by the most wonderful tact and patience that the expedition succeeded in accomplishing its work without loss of life. The Masai

are notorious cattle-lifters and great breeders, but their herds were dying by thousands of some mysterious disease, and it was only when at its last gasp that an animal could be bought, its carcase when cut up being loathsome. It was no wonder, then, that Mr. Thomson suffered dreadfully from dysentery, and a less determined man might have succumbed entirely. Yet Mr. Thomson cannot sufficiently express his admiration for a people whom he regards as the Apollos of Africa. Their physique, their language, their habits, their bearing, differ entirely from those of any other African race, though there seems little doubt that they are, by language at least, allied to the Gallas. Indeed, their own traditions point to a Galla origin: they seem to be intruders into the region between Kilimanjaro and Kenia, which is now entirely dominated by them. They are certainly not a pure race, and scattered among them are remnants of a different people, who are the pariahs of the country. Their intelligence is above that of the average African, as is indicated by the dimensions of their skulls as well as by their organisation and general bearing. Their social habits are much what we find among other races of their stage of civilisation: "morality"

FIG. 4.—*Strepsiceros Colei.*

begins only after marriage. All the unmarried men belong to the warrior class, and are permitted to use none other than animal food. Their spears, of native make, are of enormous dimensions, and their war costume is elaborately ludicrous. One strange custom is that spitting is the greatest mark of distinction you can bestow upon a Masai, and Mr. Thomson was often sorely exercised when he desired to be particularly conciliating and gracious in his intentions. This custom is, however, not without parallel: the natives of part of the southern coast of New Guinea, indeed, improve upon it by squirting mouthfuls of water on those to whom they wish to give a specially friendly welcome. What is the particular significance of the custom perhaps those who have investigated the subject of salutations may be able to explain.

As to the country itself through which Mr. Thomson passed, while part of it is desert, simply from want of water, much of it is rich in grass and forest, abundantly watered, and with a wealth of varied scenery scarcely surpassed in some of the favourite tourist resorts of Europe. Besides the two prominent mountain summits, there are several ranges of varying height, one of the loftiest and most attractive being to the south-west of Mount Kenia, and to which Mr. Thomson loyally gave the name of Lord Aberdare. "The Masai country," Mr. Thomson tells us, "is very markedly divided into two quite distinct regions, the southerly or lower desert area, and the northerly or plateau region. The southerly is comparatively low in altitude, that is to say, from 3000 to nearly 4000 feet. It is sterile and unproductive in the extreme. This is owing, not to a barren soil, but to the scantiness of the rainfall, which for about three months in the year barely gives sufficient sustenance to scattered tufts of grass. The acacia and mimosa have almost sole possession of these dreary plains, except near the base of some isolated mountain or other highland, where small rivulets trickle down, to be speedily absorbed in the arid sands. No river traverses this region, and many parts are covered with incrustations of natron, left by the evaporation of salt-charged springs. We have seen something of this lower region in the flat reach of Njiri, and the forbidding desert of Dogilani. It is not, however, to be conceived as a monotonous level. Far from it. The colossal Kilimanjaro and the conical Mount Meru belong to it. The hills of Gelèi and the Guaso N'Ebor circle round in the form of an amphitheatre, to meet the metamorphic masses of Ndapdak and Donyo Erok. Further to the west and north are the volcanic masses of Donyo Engâi, Donyo la Nyuki, and Donyo Logonot, with the hills of Nguru-mani. Except in the immediate vicinity of the higher mountains, such as Mount Meru and Donyo Engâi, the country is to a large extent uninhabited. To summarise this tract we may say that it is triangular in general shape, the apex towards the north reaching to within thirty miles of the equator, and extending beyond to Baringo as a species of trough or deep irregular cutting. The Masai are only to be found at all seasons about such favourable situations as the base of Kilimanjaro, Mount Meru, Ndapdak, Gelèi, Kisongo, to the west of Meru, Donyo Engâi, and along the edge of the plain at the bases of the bordering highlands Mau and Kaptè. The country is sufficiently characterised when the fact is stated that it is a region of late volcanic activity, which in a very recent geological period has produced the cones and craters already referred to. These results of volcanic energy may, to some extent, be accounted for—though the statement may seem to savour of reasoning in a circle—by the lower region as an area of depression having subsided or sunk from the higher level of the flanking table-lands. The northerly or higher plateau region of Masai Land may be described as rising from an elevation of nearly 5000 feet on either side, and culminating in the centre at an elevation of little short of 9000 feet—although through this very line of highest elevation runs from the Dogilani plain the remarkable meridional trough which incloses the charming chain of isolated lakes, Naivasha, Elmeteita, Nakuro, and Baringo, and which, at the last-named place, begins to widen out till it assumes the characteristics of the southerly plain of Masai Land. On the eastern half of this divided plateau rises, as we have seen, the snow-clad peak of Kenia—and the picturesque range of the Aberdare Mountains, which runs almost parallel with the central line of depression. A more charming region is probably not to be found in all Africa, probably not even in Abyssinia. Though lying at a general elevation of 6000 feet it is not mountainous, but extends out in billowy, swelling reaches, and is characterised by everything that makes a pleasing landscape. Here are dense patches of flowering shrubs; there noble forests. Now you traverse a park-like country enlivened by groups of game; anon, great herds of cattle, or flocks of sheep and goats are seen wandering knee-deep in the splendid pasture. There is little in the aspect of the country to suggest the popular idea of the tropics. The eye rests upon coniferous trees, forming pine-like woods, and you can gather sprigs of heath, sweet scented clover, anemone, and other familiar forms. In vain you look for the graceful palm—ever present in the mental pictures of the untravelled traveller. The country is a

very network of babbling brooks and streams—those of Lykipia forming the mysterious Guaso Nyiro; those of Kikuyu the Tana, which flows to the Indian Ocean through the Galla country; while further, south, in Kaptè the streams converge to form the Athi River, which flows through U-kambani to the Sabaki River."

Here is Mr. Thomson's account of his observations on Mount Kenia:—"We were now at an altitude of 5700 feet, which may be taken as the general level of the plain from which Mount Kenia rises. Kenia itself is clearly of volcanic origin, and may be considered to be a counterpart of the Kimawenzi peak of Kilimanjaro. Unlike Kilimanjaro, its volcanic forces have not changed their focus of activity, and hence it now stands as a simple undivided cone. Up to a height of 15,000 feet (9000 feet above the plain) the angle of slope is extremely low, being in fact only between 10° and 12°, a fact which would seem to show that the lavas ejected must have been in a much more liquid condition than those of Kilimanjaro. The angle in the latter is much higher, indicating that the ejections were more viscid, and consequently did not flow so far from the orifice. At an elevation of over 15 000 feet the mountain suddenly springs at a high angle into a a sugar-loaf peak, which adds a further height of about 3400 feet. At the base of the peak two small excrescences are noticeable, and some distance to the north there rises a humpy mass. This peak, as in the case of Kimawenzi, without a doubt represents the column of lava which closed the volcanic life of the mountain, plugging or sealing up the troubled spirits of the earth. The crater has been gradually washed away—having been composed, doubtless, of loose ashes and beds of lava, and now the plug stands forth, a fitting pinnacle to the majestic mass below. As at Kilimanjaro, nature has appropriately woven for its grim head a soft crown of eternal snow, the cool, calm shining of which is at once a wonderful contrast and a strange close to the mountain's fiery history. The sides of this upper peak are so steep and precipitous that on many places the snow is quite unable to lie, and in consequence the rocks appear here and there as black spots in the white mantle. Hence its Masai name of Donyo Egèrè (the speckled or gray mountain). The snow covers the whole of the upper peak, and extends some distance on either side, reaching, and indeed including, the humpy mass on the north. The peak is strikingly suggestive of an enormous white crystal or stalagmite, set upon a sooty basement, which falls away gradually into the dark emerald green of the forest region round the base."

On the north side of Mount Kenia very few streams have their origin, though on the south side they are said to be abundant. It is still more unaccountable that, except on the south side of Mount Kilimanjaro, not a stream trickles down the snow-capped mountain, a phenomenon which only actual exploration can account for. One of our illustrations (Fig. 2) shows a great lava-cap in the Elgeyo Mountains to the west of Lake Baringo. In a running survey such as Mr. Thomson made, minute observation is of course impossible; but with his experience as a field geologist and his general caution, we may accept his geological map of the region lying between Victoria Nyanza and the coast as in a general way representative of the facts. Along the coast at Mombassa we find a strip of Tertiary rocks, succeeded westwards by a broad band of Carboniferous. West and north west of this is a great area of metamorphic rocks, having their counterpart further westwards on the east side of Victoria Nyanza. Between them, in three irregular strips, lie the earlier and later volcanic series, the mass of Kilimanjaro winding its way into the metamorphic, and Kenia lying on the northern edge of the latter. That volcanic activity is not quite extinct is shown by the fact that in the Kenia region hot springs and pools are met with, and the natives have a tradition that on the site of Lake Chala, on the east side of Kilimanjaro, once stood a large and populous town.

Thus Mr. Thomson has been able to fill up in a very satisfactory manner a considerable blank on the map of Africa. He has moreover established the fact that Baringo is a distinct lake, and that the east shore of Victoria Nyanza trends much more to the north-west than we find it on Mr. Stanley's map. The combined observations of Mr. Thomson and Mr. Johnston are a valuable addition to a scientific knowledge of one of the most interesting regions of Africa.

NOTES

MANY of our readers will be pleased to learn that M. Charles Feil has, after some years' absence, returned to the active management of his celebrated manufactory of optical glass in Paris, the new firm being "Feil père et Mautois." M. Charles Feil, who is well known both for his scientific and business abilities, is grandson to M. Guinaud, who, some sixty years since, in a mode of working almost identical with that adopted by the celebrated potter Palissy, overcame the serious obstacles which occur in securing the perfect homogeneity of both crown and flint glass, and whose secrets have descended to his grandson.

IT is with great regret we announce the death, on the 7th inst., of Mr. Edward Caldwell Rye, Librarian to the Royal Geographical Society, after a very short illness, from small-pox, aged about fifty-two years. In natural history he specially made his mark as an entomologist, and for a long time was the chief authority on British beetles, on which subject he was the author of a volume in Lovell Reeve and Co.'s series of popular works on British Natural History. For several years he contributed the article "Coleoptera" to the *Entomologists' Annual*, and he was one of the editors of the *Entomologists' Monthly Magazine* from its commencement in 1864. Furthermore he was for some years on the staff of the *Zoological Record* as a contributor, and since the 10th volume of that useful publication he had been sole editor. Nowhere will his nearly sudden death be more felt than at the Royal Geographical Society, for, in addition to his ordinary duties as Librarian, that of editing the bibliographical portion of the *Proceedings* devolved upon him. Mr. Rye married a daughter of Mr. G. R. Waterhouse, of the British Museum, who, with four children, all young, survives him; and, if report be true, they are left almost unprovided for. He was a Fellow of the Zoological Society, a member of the Entomological Society of London, and the Recording Secretary of Section E at the meetings of the British Association.

WE regret to announce the death, at Paris, on February 1, at the early age of thirty-four, of Mr. Sidney Gilchrist Thomas, to whom is mainly due the basic Bessemer process. Born in 1850, he entered the Civil Service, but from his youth showed a taste for science, and especially metallurgy. The project of eliminating phosphorus by the Bessemer converter soon occupied all his attention, and, after numerous experiments at [illegible] in 1877 he took out his first patent, and commu[nicated] invention to the Iron and Steel Institute in a paper [read] Paris meeting in 1878.

THE Minister of Agriculture in Canada has just d[isallowed] Bell telephone patent void in the Dominion, the occasio[n] double infraction of the Canadian law [by the] phone Company. It appears that the [Company] phones after the expiry of two years fr[om] and that it also refused to sell instrume[nts] ing annual rentals for the lease, as in [the] States. Both these acts contravene the

UNDER the title of "The Cost of a Fog," Mr. W. T. Makins, Governor of the Gas Light and Coke Company, writes to the *Times* under date of January 24:—"Perhaps your readers may be interested to read the experience of the Gas Light and Coke Company on the occasion of last Tuesday's fog. Ninety-six million cubic feet of gas were sent out during the twenty-four hours ending at midnight on Tuesday. This quantity was an increase on that of the corresponding day in 1884, which may be taken to have been an ordinary January day, of 37 per cent., or over 35,000,000 feet. The price being 3*s.* per 1000 feet, the public had to pay this one company 5250*l.* extra on account of the fog. Nine thousand five hundred tons of coal were carbonised during the twenty-four hours to produce the 96,000,000 feet, the largest quantity we have ever sent out in one day."

THE *Times* Alexandria correspondent, in reference to the Egyptian Sanitary Board, takes occasion to mention the immense services which might be rendered to that country and to science by the appointment of a scientific microscopist and analyst to the uncontrolled charge of the Health Department. An eminent physician assures him that half the population are mentally and physically incapacitated for work, owing to the existence of certain diseases, which sanitary study might remedy.

FOLLOWING the example of the United States Geological Survey, that of Canada has lately enlarged the sphere of its operations, so as to include ethnological work in its publications. The first result of this wise measure is a volume containing copious comparative vocabularies of the chief Indian languages still current in British Columbia, for which the authors, W. Fraser Tolmie and George M. Dawson, have been collecting materials since the year 1875. In this collection, which was issued in 1884 by Dawson Brothers of Montreal, the list of words proposed by Mr. Gibbs in his "Instructions for Research Relative to the Ethnology and Philology of America," has been adopted as a basis, and his orthographic system has also been largely adhered to. The vocabularies thus comprise over 200 words of one or more dialects of every stock language spoken on the Pacific slope of the Rocky Mountains from Alaska southwards to the Columbia River. Appendices are added containing comparative tables of other native languages from vocabularies already printed, and from these tables it appears evident that, contrary to the hitherto prevalent impression, the widespread Tinné (Athabascan) family is represented on the Pacific slope in the Tshimsian group about the Nasse and Skeena rivers over against the Queen Charlotte Islands. Nevertheless on the accompanying linguistic map, which is on a large scale, this group is still coloured separately as if it were a stock language, and not a branch of the Athabascan, as is now for the first time made evident. The other stock languages of this region—Haida (Queen Charlotte Islands), Thlinkit (from Alaska to the Nasse River), Kwakiool, Aht, and Kawitshin (Vancouver Island), Niskwalli (Puget Sound), Cheheili (Washington Territory), Tshinook (Lower Columbia River), Bilhoola (Bentinck and Dean Inlets), Selish (Fraser River), Sahaptin (Right Bank Columbia River), and Kootenuha (Kootenay and Upper Columbia Rivers)—all are represented in one or more of their branches. Altogether valuable materials are here collected and conveniently arranged for the comparative study of nearly thirty languages or distinct dialects current in one of the most intricate linguistic domains on the American Continent.

THE African Association will shortly send to the Congo the apparatus required for establishing telephonic communications between certain stations on the lower river.

ACCORDING to the report of Capt. E. Backhaus, of the German ship *Carl* (published in *Hansa*), that vessel, while on her voyage from New York to Trieste, experienced an earthquake at sea on the night of December 21–22 last. For about five s[econds] the ship was violently shaken. The lamp shades were th[rown] to the ground, and the upper layers of the tins of pe[as] between decks were pitched up against the deck. She w[as] at 36° 34′ N. lat. and 22° 26′ E. of Greenwich, that is, [off] Cape Matapan in the south of Greece. Those on board th[ought] the ship had struck on a rock, and the pumps were rigged [and] set working. The sea was still, but had a whitish colour, [the] wind was east and light, and the rate was about three [and a half] miles per hour. When examination was made subsequently [no] trace of injury was found on the wood or copper outside. [The] captain was led to make a report of the occurrence at Trieste [on] hearing of the Spanish earthquake, as well as from another [ship] master, who had experienced the same phenomenon also [off the] south of Greece.

THE last four years have been a period of unusual activity [in] railway construction in Japan. How much has been [done] that period, and is now being done, is not generally [known] in Europe. The following statement on the subject is [abstract]marised from a paper communicated to the Geographical Society of Toulouse by Capt. Fouqué, Professor of Mathematics [at] Tokio. The line between Tokio and Yokohama, [about] miles in length, was opened in June, 1872; that between [Tokio] and Osaka in March, 1874, its extension to Kioto in 1877, [with] a further extension to Otsu, making the total length from [Tokio] about sixty miles, in 1879. At Otsu it reached the shores [of] Lake Biwa. What may be regarded, therefore, as a prolongation of this line is that from Nagahama, at the head of the lake, to Tsuruga, an important harbour on the sea of Japan, a distance of over twenty-five miles. There is thus a direct steam connection (as there is a fleet of steamers on the lake) between Hiogo on the Inland Sea, and the Sea of Japan on the west. On May 1 last a line was finished between the same—Nagahama and Sekigahara—with a continuation to Ôgaki, a total distance of about fifty-five miles, through the centre of the province of Mino, one of the most productive in Japan. The last line finished is that between Tokio and Tagasaki, which was opened by the Emperor on June 25, 1884. The length is about sixty-two miles, and it taps the rich provinces of Joshin, Shinano, and Boshin, the great centres of silk, tea, and tobacco cultivation. There were no serious engineering difficulties on this line, perhaps the most important of any yet constructed in Japan, for it traversed large and fertile plains. Thus the total length of the railways actually constructed in Japan is about twenty-three miles. Two short lines in course of construction are to be between Shinagawa, near Tokio, and Kawaguchi, and one from Tagasaki to Mayebashi, the capital of the silk trade. The latter is only about eight miles long, and may be regarded as complete. Of projected lines the construction of the following have been decided on, and the work should be commenced at this time: (1) one from Tokio due north through the centre of the main island to Awomori, opposite Hakodate, in the Island of Jezo. This would be one of the main trunk lines of Japan, and its length will be about 450 English miles. (2) From Takasaki to Ôgatchi, the first part of a line which will ultimately reach Yokkaichi, an important seaport on Owari Gulf, on the east coast. The length of this will be about 200 miles. (3) From Nyeda, in Shinano province (in the centre of the main island) to Niigata, the principal part of the west coast, 150 miles, and two shorter lines intended to connect important towns with neighbouring ports. It has been decided recently to construct tramways between some of the principal towns omitted in the railway scheme, the first being between Tokio and Kobe, a distance of about 700 miles. The amount of money available for public works of this description is necessarily limited, and the progress is therefore, everything considered, exceedingly rapid.

ACCORDING to a Russian journal, quoted in *Globus*, the Russian law, especially as regards murders, is now to be enforced amongst all natives under Russian rule. Hitherto the murder of a Kirghiz was punished by their own customs in the following manner:—When in an aul or in the steppe a murder has been committed, the relatives and friends of the dead man commence the search for the murderer. Sometimes he is not found until after a long interval, especially if the body is not soon found. Frequently the latter is hidden, then the flight of birds of prey is watched, and other indications are utilised by the extraordinary acuteness of the nomads. When the murderer is discovered the relations have the right to levy from him a so-called *kun*. This fine, which washes away bloodguiltiness, consists of a number of camels, horses, sheep, and clothes, a special *kun* being due to those who took part in the search for the murderer, to the person who actually discovered him, and to the judge. The fine, or *wergild*, for a woman is less than that for a man, and in the latter case it varies with the descent. Thus there would be a greater fine for killing a pure Kirghiz than for killing one whose descent was unknown. If the murderer cannot pay the *kun*, his kinsfolk must do it for him, and the payment and receipt of this fine is accompanied by a number of different customs. The occasion is a kind of festival in the aul in which the relatives of the murdered man live. Among the animals paid as *kun*, the murderer's horse must always be one. The family of the person killed have, however, the right to refuse all payment, and to demand a duel with the slayer. The latter appears in the aul of the others armed from head to foot, and mounted on his best steed; a certain distance off the avengers are stationed, and a wild race ensues. If the accused can get away from his pursuers, he is safe from all punishment; he can, however, only be pursued to the going down of the sun, and directly the latter sinks behind the horizon he is free. If he is caught he is generally put to death at once. It is remarkable that a murder rarely remains undiscovered. The Kirghiz hardly ever commit that crime for the sake of robbery; the murder generally takes place after a quarrel, or for revenge.

AMONG the various contrivances for indicating 24 hours on watch dials, one by Sturrock and Meek, mentioned in the February number of the *Horological Journal*, seems to be neat and ingenious. The dial is made with twelve holes in place of the usual figures. During the first half of the day, midnight to noon, the figures 1 to 12, placed on a disk at the back, show through; at noon the disk becomes automatically shifted so that the figures 1 to 12 are replaced by figures 13 to 24 (0); at midnight the figures 1 to 12 are again brought into view. Thus, whilst retaining the ordinary and familiar and convenient 12 hour spaces, the advantage of the 24-hour system is obtained without the necessity of keeping a double set of hourly figures constantly in view.

To the *Boletin de la Institucion libre de Enseñanza* for January 15, D. Augusto Arcimis sends an account of the meteorological branch of the observatory recently attached to that institution. The building is situated in the Paseo del Obelisco in the north of the city, where it is surrounded only by low buildings and removed as far as possible from disturbing influences. Pending the acquisition of improved instruments a mercurial barometer connected with two thermometers, and with a diameter of 4 mm., has been set up, and since last December its readings have been systematically compared with those of the barometer in the Medical Observatory. With another instrument, specially constructed by Salleron of Paris, records are taken of the atmospheric temperature in the shade, as well as of the moisture, certain modifications having converted it for practical purposes into a hygrometer similar in principle to that of Mason. The thermometer is modelled on the system introduced by Negretti and Zambra of London, while that of minima adopts the Rutherford system, both being manufactured by Secretan of Paris. To avoid as far as possible the disturbing influences to which all meteorological stations are exposed in large cities, the instruments are placed in wooden boxes, which, while exposed to the free circulation of the air, are still thoroughly protected from bad weather and from the direct rays of the sun. The Institution has also been supplied with other instruments for determining the amount of evaporation, the loss of heat by radiation, the force, pressure, and direction of the winds prevalent throughout the year. This meteorological station is thus one of the best equipped in Europe, and in fitting it up advantage has been taken of the experience already acquired from the working of similar establishments elsewhere.

THE first railway in Cochin-China was opened on December 21 last. It runs from Saigon to Mytho, the journey taking about four hours.

IN connection with the Parkes Museum a meeting will be held at the Mansion House on Friday at 3 p.m. to obtain more extended support for the Parkes Museum, so that it may be firmly established on a permanent basis. The Right Hon. the Lord Mayor will preside, and the Council hope to have the support of all those interested in promoting public health and a knowledge of the laws of hygiene.

AT the Meeting of the Council of the National Smoke Abatement Institution, preliminary to the recent annual meeting, a letter was read from the secretary of the Duke of Westminster stating that in his Grace's town house nothing had been burnt but coke, with the most satisfactory results. The Draft Report to the Annual Meeting was presented by the Secretary, to which, at the chairman's suggestion, it was decided to add a paragraph calling attention to the obsolete character of the boundaries within which the present Metropolitan Smoke Act is operative, and pointing out the necessity for a short amendment Act aiming at a rectification of the boundaries, and the necessity for a firmer and fuller application of the provisions of the Act to certain industries in which smoke abatement is now much easier than it was at the time when the present Act was passed. It was resolved to communicate with the Home Secretary, calling his attention to the documents which had been already forwarded to him, and to the paragraphs in the Report relating to the nominal nature of the fines imposed by the magistrates in cases of infringement of the Act, and ask him whether, under the circumstances, he would be willing to issue a circular calling the attention of the police magistrates to the evils which result from the difficulty of obtaining a due enforcement of the law. It was further resolved to issue a separate memorandum, in the form of a leaflet, putting forward some information as to the conditions to be considered in the choice of grates, in the burning of fuel, and in the general treatment of a coal fire.

PROF. SIDNEY COLVIN, Slade Professor of Fine Art in the University of Cambridge, will give two lectures at the Royal Institution, on Tuesdays, February 17 and 24, on "Museums and National Education."

SOME of the fish in the Salmonidæ tank at the South Kensington Aquarium have recently been spawned, the species operated upon being the *S. levenensis*, *S. fontinalis*, and the *Gilleroo* trout of Ireland. The eggs have been deposited in suitable hatching boxes, where they afford satisfactory evidence of ultimate success. It will be particularly interesting and edifying to note the result on account of the prolonged captivity of the fishes from which the eggs were spawned.

THE fine aquarium on view during the Health Exhibition will naturally be in existence during the forthcoming Inventions Exhibition. In addition thereto will be shown a very large collec

tion of fish culture appliances showing the process of hatching, the mode of dealing with the fry after losing their umbilical sac, and the best means of artificially feeding them until they have reached that stage in their existence when they are able to provide for themselves. A special building is to be erected for this purpose in proximity to the aquarium, which is now in course of construction. This section of the Exhibition, which will be under the entire direction of the National Fish Culture Association, promises to be a source of much attraction and interest to the ichthyological world.

An experiment has lately been tried by the Secretary of the National Fish Culture Association at South Kensington to test the highest temperature endurable by various species of fish. To this end several specimens of the following fish were selected for the trial, viz. the carp, gudgeon, dace, roach, perch, minnow, golden tench, common tench, trout, and salmon, all of which were deposited in cold water registering 53°. The temperature was then gradually increased by the infusion of hot water through a tube which caused the temperature to rise steadily. None of the fish, however, exhibited signs of fading vitality until the thermometer recorded 82°, when a perch became prostrated; and shortly afterwards its tenements followed its example in rapid succession in the following order:—Roach, 82½°; salmon, 83°; minnow, 85°; gudgeon, 85½°; dace, 86°; common tench, 88°; golden tench, 88°; carp, 91°.

So as to further test the efficacy of brandy as a fish restorer, about which much has lately been said, each fish on showing signs of exhaustion was removed from the water, dosed with a small quantity of brandy, and replaced in the tanks from whence it was taken. The operation proved highly successful, for on inspection the following day all the objects of the experiment were found swimming about as usual, and thoroughly restored to their normal exuberance, with the exception of the dace, which succumbed to the severe ordeal through which it had passed.

The additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. F. W. Robinson; a Royal Python (*Python regius*) from West Africa, presented by Mr. A. H. Berthoud; a Long-eared Owl (*Asio otus*), British, presented by Mr. R. Farren; two Kagus (*Rhinochetus jubatus*) from New Caledonia, purchased.

GEOGRAPHICAL NOTES

In a special article communicated to the *New York Tribune*, Lieut. Greely unfolds his views upon future Arctic exploration. Of the five well-known routes to the Pole, he advocates the Franz Josef route as the only probable one. Lieut. Greely shows by all the experiences of Arctic travellers, from Sir Edward Parry downwards, that continuity of land, with northern trend and western aspect, and a secure harbour easy of access, together with good ice for sledging operations, are necessary desiderata for Arctic exploration. He maintains that all these conditions are fulfilled in the fifth route—viz. that by Franz Josef Land. "This route," continues Lieut. Greely, "presents unusual chances of success with the minimum of danger. It is more than possible that an English expedition will enter these waters. Chief Engineer Melville, U.S.N., has in view an expedition by this route, and his varied Arctic experiences and indefatigable energy mark him as a man peculiarly fitted for this work. It is therefore to be hoped that he will be given the desired opportunity. Two ships with about sixty men and officers would be needed. One vessel should winter in Eira Harbour or some secure point near by, while the second should be pushed as far northward as possible, preferably by Austria and Rawlinson's Sounds, but, if that is not possible, along the west coast of Franz Josef Land beyond Cape Ludlow. The vessels should be provisioned for three years, and the crews should be quartered in temporary houses to be erected on shore. August and September there, as in Smith Sound, are undoubtedly the most favourable months for ice navigation. In ... a bad year for ice the vessels should rather return, to ... expedition the year following, than adventure the experience ... the *Tegethoff*. After full suggestions and recommendations ... to the command and outfit of the expedition, covering ... branch of the subject, the writer expresses a doubt whether ... United States Government will extend any aid to Arctic explo... tion for years to come, but none the less does he believe in ... propriety and certainty of future Arctic work. In conclud... his article Lieut. Greely says:—"The expedition suggested ... Lieut. Ray, United States Army, at the meeting of the Brit... Association at Montreal, should receive the attention and ... port of scientific men. The magnetic pole of Boothia F... Land, located by Ross in 1831, has probably changed its p... tion in the past fifty years. Its re-location would be an ... portant contribution to science. With a home station at Repu... Bay or in Wager River, I believe this work could be done w... out great expense or serious danger. The benefits to be deri... from such an expedition would not be confined to terrestr... magnetism. As regards ethnology, botany, and natural histo... the country around King William Land is substantially ... blank."

An interesting account of recent Norwegian explorations ... the Spitzbergen Seas will be found in yesterday's *Times*. Se... ral new islands have been discovered to the east of King Karl ... Wiche Land. These explorations show that the year 1884 w... a very remarkable ice-year. The west side of Spitzbergen w... blocked by a belt of land-ice the whole summer through, wh... the east side, which is nearly always blocked with ice, was mo... open than it has been for many years. These conditions, th... seems little doubt, depend on the prevailing direction of t... winds.

According to the *American Naturalist* three expeditio... have been despatched during the last summer to explore t... lake region reported to exist in the north-eastern part of t... provinces of Quebec and in Labrador. One went by way ... Lake St. John, another by the River Betsiamits, and a thi... from Newfoundland. The last has orders to land scientif... observers at various points upon the coast of Labrador, who ... they will spend the winter. Little that is definite appears to ... as yet known respecting the actual dimensions of Lake Mista... sini and other bodies of water in this region. A French su... mary, writing in 1672, says that this lake is "believed to ... so large that it took twenty days to walk around it." M... Burgess affirms that it is 150 miles in length, and abounds ... deep bogs. An old trader of the "Compagnie de Postes ... Roi," who was stationed on it for several years, estimated ... least width at ninety miles. The account of 1672 mentio... another lake, "ten days' round, and surrounded by lofty moun... tains." These lakes appear to occupy a depression similar ... that occupied by Lakes St. John, Temiscaming, and ma... smaller lakes to the southward, and Silurian limestone has be... observed in Lake Mistassini as well as at Lake St. John. T... former lake is supposed to be about 1300 feet above the se... and the land between it and Lake St. John to the south is on... 300 feet above the sea. The plain around it is said to be ve... fertile, and attention has recently been called to the magnificen... forests and fertile soil of the country around Hudson's Bay ... the north of it. The explorations now in progress will doubtle... open up extensive areas for colonisation, besides adding large... to our geographical knowledge.

La Gazette Géographique announces the death, in Tonquin, ... M. Stocker, who perished recently in an expedition against th... Muongs on the Red River. M. Stocker, who was a native of ... Alsace, travelled for thirty years in the United States, havi... explored specially the Rocky Mountains and the territory ... Alaska. He returned recently from California to France, an... was despatched by the Government to investigate the mineral ... wealth of Tonquin, where he discovered the auriferous deposi... of Myduc. His reports on the subject were not encouraging f... the development of mining enterprise there, as he declared that th... value of the mines had been greatly exaggerated. He was als... dead during one of the skirmishes in the Muong expedition.

Sixteen "*brigades topographiques*" embarked at Marseille... on January 31, fourteen for service in Algeria and two in Tuni... These brigades are under the command of an officer, at t... engineer, and of an official of the geographical department o... the War Office in Paris. The whole include seventy-two officer... each accompanied by two soldiers and a native shareholder...

and tents for each officer are to be
r mules. They will commence their
of each of the three Algerian pro-
ntered as they will be singly over
midst of semi-subjugated tribes, will
ic. They will probably return to

CATALOGUE OF EARTHQUAKES[1]

THE importance of earthquakes as factors in geology tends to be more and more appreciated, and the seemingly increased seismic activity so strongly manifested in different quarters of the globe during the last few years has greatly stimulated the interest in, and the study of, these wonderful phenomena. Amongst many contributions to this branch of geology, have appeared quite recently, this catalogue and map, of which we have given the title, and which have followed other papers by the same author relative to this series of phenomena, published in the *Proceedings* of the Royal Irish Academy.

The earthquake catalogue and map now given by Prof. O'Reilly is based upon a very interesting relation of jointing and fissuring to the physical geography of a country, but more particularly to the coast-line directions. This relation he has shown to be very marked for the east coast of Ireland (see *Proc. Roy. I. Acad.*, 2nd series, vol. iii. ; *Science*, No. 8, May, 1882, and vol. iv. ; *Science*, No. 2, 1884); and, considering that much of the fissuring of the earth-surface is mainly due to earthquake action, he looks upon the systems of jointing and fissuring of a country, and consequently their correlated coast-lines, as so many records of past earthquake action ; the only ones, in fact, left us in many cases, and (taking into consideration the poverty and meagreness of historical records in this respect) the most valuable records of these phenomena we have extant. On the other hand, the lists of Mallet, Perrey, Fuchs, &c., present earthquakes in a purely chronological order, are difficult to consult and but little accessible, and in them the events stand out independently, and to a very great extent without apparent connection one with the other, while we know that geological change is the result of a sum of actions taking place continuously in certain localities, and extending through immense durations of time. It has seemed to the author of the present "Catalogue" that it would be useful to present the earthquakes of the three kingdoms in a summarised and connected form, and for that purpose arranged alphabetically, so that it may be possible to ascertain for a given point or locality the sum of earthquake action having occurred therein during historical time. The "Catalogue" thus formed merely gives the years of occurrence for a given place or district, and in this manner indicates frequency of occurrence sufficiently, while serving at the same time as a sort of year and place index for the larger collections. From it he has been able to represent graphically the distribution of earthquakes over the three kingdoms by adopting conventional tints and marks to indicate extent of action and frequency of occurrence, the only factors which it is possible at present to so represent.

From this map it would appear that Great Britain has been much more subject to shocks than Ireland during the period embraced by the records. That as regards Ireland the points of more frequent action lie near the coast or on it ; that in Great Britain the south coast presents a number of points of activity situated approximatively on a same line, in all probability con-

[1] "Catalogue of Earthquakes having occurred in Great Britain and Ireland during Historical Time ; arranged relatively to Localities and Frequency of Occurrence, to serve as a Basis for an Earthquake Map of the three Kingdoms." With Map. By Jos. P. O'Reilly, C.E., Professor of Mining and Mineralogy, Royal College of Science, Dublin. (*Trans. Roy. I. Acad.*, vol. xxviii. ; *Science*, part xvii., September, 1884.)

nected with a system of jointing corresponding to the general direction of the coast; that therefore the observed connection between volcanoes and coast-lines would hold good to a certain extent as regards these and earthquake action, so intimately related to volcanic action; that, as has been lately remarked by Mr. Wm. White in NATURE (December 25, p. 172), Lancashire is apparently a centre of frequent action, and that there may be a further relation to be found between coal-fields and earthquakes than that recognised up to the present.

It is certainly interesting to note that many of the localities affected by the earthquake of 1884 in the south-east of England lie on or quite near a great circle, which PROF. O'REILLY designates "the west coast of Morocco great circle" (that is a great circle of which the starting-point or part is a portion of that coast lying between Cape Blanco and Cape Juby), traced *à priori*, and which was shown on the Earthquake Map of Europe submitted by him at the Swansea meeting of the British Association in 1881. It will be interesting to note to what extent the complete report on that earthquake, which may soon be looked for, will correspond with his theoretical lines.

As a first attempt to graphically represent the earthquakes of a country relatively to their frequency, Prof. O'Reilly's map has much to recommend it, and, more fully developed and more completely worked out, such maps may yet be considered (to use his own words) as "the necessary *pendants* of geological maps."

JAPANESE LEARNED SOCIETIES

WHEN the Japanese Government decided to participate in the Health Exhibition last year, and to devote special attention to the educational portion of their section, they issued a small pamphlet relating to modern Japanese education. This explained in full the national system organised and put in working order in the last ten years; it dealt with the various classes of schools, from Kindergartens to the University, the technical schools, libraries, and educational museums, the history of ancient Japanese education, &c. The pamphlet showed that the Government of Japan was doing its duty so far as education is concerned; but the reader was left to collect for himself how far the people were following in the wake of their rulers. Since the close of the Exhibition the Japanese Commissioner has re-issued the report, with the addition of a statement of the various learned societies formed for purposes connected with science, literature, and education in that country in recent years. These are purely private associations; some of them are confined to localities removed from the large towns, and bespeak a wide and general interest in these subjects amongst the mass of the people themselves. The work of organising these, when the spirit once existed, cannot have been great, for the Japanese have had for ages their associations of men possessing common tastes, or a common love for a particular subject, whether literature, education, fencing, chess, the study of medicine or of Chinese. These organisations are quite familiar to them, and the work of running the new metal into the old moulds was doubtless not a very difficult one. Accordingly, Mr. Tegima's list is a full one, and here and there it might be suggested that two, or even three, of the separate societies could amalgamate with benefit. Amongst those noted we find the educational society of Japan, which has for its object the study, improvement, and advancement of education; various local societies also intended for the improvement of educational methods in their respective districts; the Seismological Society, perhaps the best known of all in Europe. There are two branches of this, the foreign and the native, the former being the parent society. The "Society of Specialities," which has in view the study "of various special branches of science." The Physical Society, devoted exclusively to the study of the higher phy-ics; there appears to be a second Society of Physics, "composed of professional scholars for the purpose of inquiring into the principles [of physics?] and of interchanging knowledge among the members"; the Mathematical Society for the study of the higher mathematics, and also to translate and compile works on that subject. Among the associations for more general objects we find one of French scholars, foreign and native, for the study of that language, and the general interchange of knowledge, one for the study of the moral sciences, another devoted to European and Asiatic philosophy. The French scholars are not allowed to have it all their own way, for a rival devotes its energies to the study of the German language and laws; Hindoo philosophy also has its own special votaries who have formed themselves into association for the investigation of this misty subject. T Biological Society of the University of Tokio (founded by Fr Morse) is among the most energetic of young Japanese soc ties; the Association for the Translation of the Technical Ter of Physics is a most necessary one, and has a difficult and sponsible duty under the present system of translating to fal Sooner or later Japanese and Chinese students will have adopt most of the technical terms of all departments science employed in the West; the present plan of seeking translate them in a rough and fanciful way, and thus forcing student to learn a new language before he can learn a scien is too clumsy and unsatisfactory to last. Why, for exam oxygen should not be called oxygen by the Japanese stude instead of by some Japanese compound term which is not in least more explanatory to him, is not quite clear. Meantime society which will exercise a supervision over the translation technical terms, and thereby secure uniformity, cannot fail to useful. The Chemical Society, besides devotion to the science chemistry, has also for one of its objects the establishment o regular terminology. The Engineering, Law, Agricultural, Fi Arts, Medical, and Pharmaceutical societies speak for the selves. A second medical society seeks to secure the propag tion of sound notions of elementary medicine amongst the co mon people; in this it is assisted by the members of the Soci of Hygiene, who diffuse a general knowledge of sanitary m ters. It is pleasant to see that old Japan is not forgotten this crowd of young associations. The members of a Soci of Letters study all branches of Chinese and Japanese lite ture, while the "Society of Japanese Literature" devotes its wholly to the study of the etymology and syntax of the Japan language and to the more general employment of the ancie syllabaries, in place of Chinese characters, in writing. A thi literary society has for its object "the interpretation of t moral principles. It aims also to encourage good customs, promote literature, to educate youth, to diffuse knowledge, a to cultivate moral nature"—a tolerably comprehensive pr gramme. Finally, the recent Fisheries Exhibition has gi rise to a Japanese Marine Product Society.

Mr. Tegima's statement is an incomplete one. It de mainly with associations existing in the capital, and mak little reference to any in other large towns in the Empire, su as Osaka, Nagoya, Niigata, Nagasaki, &c. And even as a of the Tokio societies it is incomplete. No mention, for ample, is made of the most numerous, wealthy, and influen of all—the Geographical Society of Japan; nor is the Dendr logical Association mentioned; nor is reference made to new and interesting society called the *Roma-ji-Kwai*, which for its object the substitution of Roman letters in Japan for Chinese characters and the native syllabaries. This Spelli Reform Association has set before itself a huge and unde reform, in comparison with which that of our own Spelli Reform Society is trifling and superficial. Its objects, howev appear hardly practicable, if one may venture to use that exp sion, of any reform in Japan. But enough has been said show that the seed sown with such care by the Government producing a rich harvest among the people of Japan.

THE PROPOSED TEACHING UNIVERSITY FOR LONDON

A LARGELY-ATTENDED and influential meeting of t Association for Promoting a Teaching University London was held last Thursday at the rooms of the Society Arts, John Street, Adelphi, under the chairmanship of Lo Reay, the President of the Association, whose objects are (1) the organisation of University teaching in and for Londo the form of a Teaching University, with faculties of a sciences, medicine, and laws; (2) the association of Univer examination with University teaching, and direction of both the same authorities; (3) the conferring of a substantive vo in the government of the University upon those engaged in work of University teaching and examination; (4) existing stitutions in London of University rank not to be abolished ignored, but to be taken as the bases or component parts the University, and either partially or completely incorpora with the minimum of internal change; (5) an alliance to established between the University and the professional porations, the Council of Legal Education as representing

yal Colleges of Physicians and of

they last met several things had
e of which was the appointment by
a Committee to inquire into the
eme, or something like the scheme,
embers of that association when
ther. The sub-committee of the
dered since how this move in the
of London affected their prospects
red at the conclusion that the best
to ask the association to allow
a committee appointed at that
all the various bodies who had
for the sub-committee's scheme
which committee any other pro-
ers of the association who in any
details of the scheme that had
ommittee to be appointed would
they had finally determined upon
d as a result of negotiation—to
f members of the association for
ght this was a practical way of
d complicated problem. That
certainly looked much more
much more rapid support in
ters of the movement originally

rk before them was one of ex-
t did a change in many respects
iversity and the placing it upon
and this, again, involved a great
s of the University of London
f them were so independently
at if those various constituent
University—were to work to-
ould understand what relations

nsly adopted.

Mr. Erichsen seconded, that
ng thirteen gentlemen:—The
J. W. Cunningham (King's
iversity College), Mr. John
Norman Moore (St. Bartho-
d (St. Thomas's Hospital),
r. R. Stuart Poole (British
(Guy's Hospital), the Rev.
rof. Warr (King's College),
ge), and Sir George Young,

at the claims of science to
ld not be ignored. Further,
mode to ascertain all the
derived with regard to the
e teaching connected with

hat the scheme which the
ended to be binding upon
e end that a plan might be
eptable to King's College,

f having two Universities,
and the other a teaching
work, and it was not a
as desirable. His feeling
ble alliance between the

examining University of the present and the teaching University of the future.

The Chairman expressed with how much regret he left that scene of action. He was sure that a very great work remained to be done in the future, and that that work would have to be done with a great deal of tact. Certainly it would have to be achieved by setting aside any notion of establishing in London any kind of ideal University. They had to co-operate with existing corporations, with existing bodies, which had hitherto done exceedingly good work, which were all manned by an extremely distinguished *personnel*—a *personnel* whose ideal it had been to do University work without having a University, and which *personnel* he hoped in the future would have at their disposal the University to which their labours had fully entitled them. He did not say this because he himself was guiltless of having mentioned what he believed to be an ideal University, for he had been guilty of such an escapade in the address which he delivered at St. Andrew's University. There he distinctly laid down what he thought to be the lines on which a University ought to be reformed; and, of course, what he advocated for the Scotch Universities he should in the main—of course there were features applicable to Scotch which were not applicable to the London University—also advocate for London. But in London the problem before them was to unite all the interests, to create a federation of interests, and to recognise the work which had been already achieved with the desire to make that work for the future more efficient, without in any way encroaching on autonomy where autonomy had hitherto proved sufficient, but where autonomy had not before proved altogether sufficient, then, to supplement it by that bond of union by which institutions and empires became great. He resigned his position as President of the Association with the wish—nay, the determined expectation—that they would succeed. He had seen how the work had been thus far done, and how determined had been those with whom he had had the honour to associate to carry the movement to a successful issue.

Sir George Young expressed how greatly they were indebted to the President for the services he had rendered in the past. The services of a very good successor had been secured in Lord Rosebery, whom he (Sir G. Young) proposed as the future president of the association, while thanking Lord Reay for his valuable services.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The second election to the Board of the Faculty of Natural Science was held on February 6. The five retiring members were re-elected, and to make the number of elected members equal to that of the professorial (*ex officio*) members, four new members were elected. After a ballot the following were chosen:—Mr. W. W. Fisher, Aldrichian Demonstrator of Chemistry; Mr. H. B. Dixon, Trinity; Mr. J. Griffiths, Jesus, and Mr. E. H. Hayes, New College.

The Examiners for the Burdett-Coutts Geological Scholarship give notice that the examination will begin on February 23.

An examination will be held at Merton, beginning on June 23, to elect to one Natural Science Scholarship (80*l*.) at Merton, and one at Corpus Christi College. The examination will be in Chemistry and Physics. Candidates must be under nineteen years of age.

On March 17 an examination will be held at Jesus in Physics, Chemistry, and Biology. Candidates must be natives of Wales or Monmouthshire, or born of Welsh parents, and must be under nineteen years of age.

An examination will be held at New College beginning on May 7, to elect to a Natural Science Exhibition (50*l*. value per annum). The examination will be in Chemistry and Biology.

AT a meeting of the Aslmolean Society in the Theatre of the University Museum on Monday, February 16, Prof. Burdon-Sanderson will read a paper "On the Study of Contagion with a view to Practical Measures."

SCIENTIFIC SERIALS

THE last number (13) of the *Journal of the Straits Branch of the Royal Asiatic Society* contains much information on the Malay Archipelago. Mr. de la Croix continues his translation of M.

de Quatrefages's work on the pigmies, the present instalment dealing with the Asiatic pigmies or negritos, and the negrillos or African pigmies. The general conclusion to which the writer comes is that modern science has erred in rejecting all that has been written on this subject by the ancients, for in the midst of many exaggerations and fables there were many facts. He finds it impossible, in the present state of our knowledge, to offer a satisfactory solution of one of the most curious points connected with the geographical distribution of the human race, viz. the narrow resemblance between the Asiatic negritos and the African negrillos, separated as they are by a vast space and by numerous and different races. Are these affinities the result of a common origin? A paper containing a translation of a Dutch account of Malacca, written in 1726, follows this, and is itself succeeded by a long one by Mr. Maxwell, of the Straits Settlement Civil Service, on the laws and customs of the Malays with reference to the tenure of land. The Rev. J. Tenison-Woods prints two lectures on the stream-tin deposits of the protected State of Perak in the Malay peninsula, and the volume concludes with two accounts of travel, one through the State of Kenaban in the peninsula, the other along the Tawaran and Putalan rivers, which are said to rise in the great mountain Kina Balu, and flow through North Borneo. We observe, also, the prospectus of a very necessary work—an English-Malay dictionary, which, it is suggested, should be translated from Mr. Klinkert's Dutch-Malay dictionary.

Journal de Physique, vol. iv. January.—J. R. Benoit, construction of standard prototypes of the legal ohm. M. Benoit, who was associated with MM. Mascart and de Nerville in the official French researches at the Collège de France, has, at the request of the Minister of Posts and Telegraphs, prepared standards in mercury to represent the legal ohm. This paper gives an account of the methods of calibrating and preparing the tubes for four exact standards. It remains to be seen whether these will prove as permanent as standards constructed in platinum-silver or iridio-platinum alloy.—H. Pellat, on the cause of electrification of storm clouds. Discusses the observations of atmospheric potential at different levels, and concludes that the negative charge of the soil surface is explicable on the hypothesis that it is continually renewed by the falling of negatively charged rain.—E. Bouty, on latent heats of vaporisation. Deduces the approximate law that the latent molecular heats of bodies measured at their normal boiling temperatures are proportional to the squares of these temperatures; tabular evidence is given in support.—E. Bouty, on the specific heat of saturated vapours. Gives a new formula.—Em. Paquet, determination of the ratio of the two specific heats of gases. Describes a modification of Cazin's method, in which the desired change of pressure is brought about by a column of mercury, as in Geissler's mercurial pumps. The deduced value for air is 1·4038.—J. Macé de Lépinay, method of measuring the interior diameter of a barometric tube. Ingenious application of optical laws to deduce internal diameter from the apparent diameter, assuming the refractive index of glass.—G. Quincke, on the measurement of magnetic forces by means of hydrostatic pressure. Abstract of paper in *Philosophical Magazine*, 1884.—W. van Beets, on normal elements for electromotive measurements. Abstract from *Philosophical Magazine*.—K. Angström, a new geothermometer. An underground mercury thermometer is read by means of an index attached to a rack and pinion, which is operated from above. When contact is made with the mercury an electric bell rings, and the index is read off.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, February 5.—"The Relation of Bacteria to Asiatic Cholera." By E. Klein, M.D., F.R.S., Joint Lecturer on General Anatomy and Physiology at the Medical School of St. Bartholomew's Hospital, London.

I propose to bring before the Royal Society the results of an inquiry into the etiology of Asiatic cholera, undertaken, at the instance and expense of the Secretary of State for India, by myself, Dr. Gibbes, and Mr. Alfred Lingard while in India. This investigation will be published *in extenso* by the India Office, but permission has been granted to us to bring to the notice of the Society some of the more important points of our inquiry, particularly those regarding the relation of bacteria to Asiatic cholera. I shall supplement them by giving the result of further observations which I have made since my return from India.

As is now well known, Dr. Robert Koch, in an extensive inquiry into the etiology of cholera in Egypt, Calcutta, and France, 1883-84, undertaken by him, Drs. Gaffky and Fischer at the instance of the German Government, has arrived at certain conclusions, which, briefly stated, are these:

1. In all persons suffering from Asiatic cholera there occurs in the rice-water stools during the acute stage of the disease certain well-characterised bacteria, which, on account of their curved shape, Koch called "comma bacilli."

2. These comma bacilli are mobile rods, of small size, of about the same thickness as tubercle bacilli, but only of half that length; they are always more or less curved, sometimes as much as to form half a circle; they vary in length according to the state of growth; they occur either singly or in couples, in the latter case arranged like an S.

3. The comma bacilli occur in great numbers in mucus flakes as well as in the fluid of the choleraic evacuations. They occur in the lower part of the ileum of persons dead in the acute stage almost to the exclusion of other bacteria, and in such great numbers that the lower part of the ileum may be considered to contain almost "a pure cultivation of comma bacilli."

4. The mucous membrane of the ileum, particularly that of the lower part, around and in the lymphatic glands located here—the solitary and Peyer's lymph-glands—exhibits in typical and rapidly fatal cases characteristic alterations: loosening and detachment of the epithelium of the surface and of that lining the glands of Lieberkühn; swelling and congestion of the blood-vessels of the mucous membrane, particularly at the peripheral portions of the lymph glands. These alterations are due to the presence, growth, and multiplication of the comma bacilli in these tissues, and the disease cholera is caused by the production on the part of these comma bacilli, and by the absorption on the part of the system of a special chemical ferment.

This state of the presence of the comma bacilli in the tissues is best pronounced in the lower part of ileum; higher up it is more limited, and gradually diminishes, and finally disappears in the upper part of the small intestine.

5. The blood and other tissues are free of any organisms.

6. The comma bacilli grow well outside the body at the ordinary temperature of the room, but better still at higher temperatures up to 38° or 40° C. They divide transversely; after division the two offsprings may remain joined end to end with shape of an S, and by further division they may grow into a spiral-like or wavy form. They grow well in the mucus flakes taken from the intestine, and placed on linen kept in a moist cell; they grow well on potato, in broth, in Agar-Agar jelly, in solid nourishing gelatine mixtures (gelatine, peptone, and beef extract). In the latter substance they exhibit a peculiar and definite mode of growth not seen by Koch on any other bacteria. The comma bacilli require for their growth an alkaline medium; they are killed by acid, by drying, and various antiseptic media.

7. On account of their constant occurrence in the intestines of patients suffering from Asiatic cholera, on account of their absence in all other diseases of the intestine, and on account of their peculiar mode of growth in nourishing gelatine, Koch vindicates for these comma bacilli not only an important diagnostic value, but also considers them as the true cause of cholera.

8. Since his return to Germany, Koch has convinced himself of the correctness of the observations of Nicati and Rietsch, who maintain that cholera can be produced in dogs and guinea-pigs by injecting directly into the small intestine of these animals the comma bacilli taken either directly from the choleraic evacuations, or from artificial cultivations.

Our investigations enable us to say this:

1. Koch's statement as to the constant occurrence of comma bacilli in the rice-water stools of cholera patients is correct; the comma bacilli vary greatly in numbers in different stools and in different cases, in some being exceeding scarce, in others numerous.

2. These comma bacilli vary greatly in length, some being twice and three times as long as others, some well curved as much as to form half a circle, others showing only just a slight bend. The name "comma bacillus" is inappropriate, as in reality they are vibrios.

3. The comma bacilli occur in the mucus flakes of the rice-water stools as well as in those taken from the ileum of a person

Linnean Society, February 5.—Mr. John Gray, F.L.S., Vice-President, in the chair.—Mr. John Hodgkin was elected a Fellow of the Society.—A paper was read on the Arboreal Grass Poa in the Neighbourhood of the Base in Bengal and Cashmere, by Prof. Marion Duncan and W. Ellis.—Mr. [illegible] read a paper on fossil [illegible] and on the [illegible] of Cretaceous and Tertiary [illegible] Mr. W. [illegible] Thiselton-Dyer, F.L.S., [illegible] Mr. W. [illegible] Thiselton-Dyer, F.L.S., [illegible]

and G. Bémont.—On vincetoxine, by M. Ch. Tauret. This term, "vincetoxine" (from Vincetoxicum, the common name of the Asclepias), is applied by the author to a new glucoside, to which is due the remarkable property possessed by the aqueous solution of the hydro-alcoholic extract of the Asclepias root of clouding when the temperature is raised, and becoming limpid when lowered. Vincetoxine has the same centesimal composition as glycyrrhizine, $C_{44}H_{66}O_{19}$.—On the signification of the polarimetric experiments executed with the solution of cotton in the ammoniacupric reagent; polarimetric researches on this reagent, by M. A. Béchamp.—On a particular case of catalytic action.—On the composition of the ashes of the Equisetaceæ; its application to the formation of coal, by M. Dieulafait. The author finds that the Equisetaceæ and other typical plants of the Carboniferous epoch contain a much larger proportion of sulphuric acid than those of the present epoch. In this fact we have the natural explanation of the large quantities of sulphur and of sulphate of lime present in all kinds of coal. The sulphur and sulphate entered into the original composition of those plants to whose decomposition are due the carboniferous formations.—On the various cetaceans cast up on the French seaboard during recent years, by M. Georges Pouchet.—Note on the influence of sudden barometric pressure on earthquakes and volcanic activity, by M. F. Laur. Arguing from the fire-damp explosions in mines and other analogous phenomena, the author concludes that all underground disturbances are due to abrupt atmospheric changes communicated even through the medium of the ocean to the crust of the earth. Volcanic eruptions are relatively superficial phenomena due to the expansion of the internal gases when a rupture of equilibrium takes place. Hence they are all the more violent the nearer they are to the surface, and the more closely connected with previously existing terrestrial vacuums.

Berlin

Physical Society, January 23.—Dr. Kayser laid before the Society a photograph of lightning taken in France and probably under the same minimal atmospheric pressure as that under which he had himself taken his recently-published photograph, the lightnings in France having been photographed three days earlier than those in Berlin. On the small gelatinous membrane sent to Dr. Kayser, still better than on that, on an enlargement of the original prepared by the speaker, there was presented very beautifully to view the extraordinarily manifold ramifications of the lightning. From the lowest part of a dark cloud a broad flash of light was seen to dart forth and throw off many fine branches, which again united multifariously, the junction at one place between one branch and another showing a broader line, while at other places the flashes appeared double.—Dr. Lummer spoke on the interference phenomena produced by two plain parallel glass plates. He briefly adduced the experimental results, already published by him, of an investigation of his own, according to which, at small angles of the glass plates, namely, up to as far as 60', the interference phenomena represented a circle passing, with increasing angles, into an ellipse, the axis of which at 90' were as 1 : 2, until, on still further enlargement of the angle, the ellipse became transformed into a straight line, which soon in turn, and till the angle of the plates approximated to 180', changed into a hyperbola. The speaker developed at large the theory of the phenomenon, and deduced the formulæ, which, on inserting the numerical data, were found to coincide remarkably with the experimental results.—A communication from Dr. Müller-Erzbach, designed for the *Verhandlungen*, had been given in and was read. Dr. Müller had sought to determine the sphere of action of the molecular forces by the thickness of the layers arising from the adhesion on solid surfaces of gases and vapours. He chose for his experiments pulverised oxide of iron and carbon disulphide. The latter became, at first very strongly, and then with abating intensity, condensed by the oxide. After four days the quantity of carbon disulphide absorbed in twenty-four hours had sunk to less than 1 mg., without, however, entirely disappearing. By microscopic measurements of the grains of oxide of iron, the author approximately calculated the magnitude of the absorbing surface, and from the quantity of the absorbed carburet of sulphur the thickness of the layer of vapour held fast by adhesion. From the circumstance that the absorption of the vapour very rapidly diminished and after a few days became quite inconsiderable, Dr. Müller-Erzbach concluded that it was not the quantities of vapour at first condensed which drew in those later also ...bed, but that the whole absorbed layer of vapour got to be held fast through ... hesion by the surface of the iron, and in this way he arrived ... values bearing on the sphere of action of molecular forces ... far surpassed all that had been hitherto obtained.—Prof. ... Prof. Neesen directed attention to the disadvantage of having ... but one term for two different meanings, such, for example, ... the word "Gewicht" (gravity, weight), which was employed ... signify both a force and a mass, a confusion which often led ... inconveniences. Scientifically either the force or the ... should be called Gewicht, the other being denominated ... another name. The debate which this question gave rise ... was to be continued at a future sitting.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share being given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and is conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharine, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nourishing" Tonic, and very much recommended by Medical men.

HOLLOWAY'S OINTMENT

AN INFALLIBLE REMEDY

For BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES and ULCERS. If effectually rubbed on the Neck and Chest, it cures SORE THROATS, BRONCHITIS, COUGHS and COLDS; and for GOUT, RHEUMATISM, and all Skin Diseases it is unequalled.

NORTH BRITISH AGRICULTURIST

the only Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377, High Street, Edinburgh; and 142, Queen Victoria Street, London, E.C.

Money Orders payable to CHARLES ANDERSON, Jun., Edinburgh.

A MEDICAL NOVEL.

CHARLEY KINGSTON'S AUNT.

A Study of Medical Life and Experience.

By PEN OLIVER, F.R.C.S. Second Thousand. Crown 8vo, 6*s*.

"A novel, written by a physician, with a medical student for its hero, would deserve a few words of notice at our hands even if it were of less conspicuous merit than this interesting volume. . . . The plot turns upon a highly dramatic incident, but it is well worked out, and the interest is well sustained until the mystery is fully explained. . . . The scene is laid in one of the best known of our medical schools of London, and old students there will have no difficulty in recognising the truth of several of the portraits which are incidentally sketched. Apart from its technical interest, this book will secure attention by its vigorous writing, its many well-touched pictures of life and character, its clever incidental use of a picturesque and fading rustic dialect, and its side-references and just compliment to some of the social traits of medical character; . . . with touches indicating an intimate knowledge of medical society, and a bright insight into some of the best sides of medical life and character"—*British Medical Journal.*

". . . To every practitioner who wishes to renew the memories of his youth the book may be confidently recommended as the companion of an idle hour."—*Medical Times.*

"'I want to make your flesh creep,' said the Fat Boy to the old lady at Dingley Dell. That is what Mr. Pen Oliver, author of 'Charley Kingston's Aunt,' wants to do to his readers, and does very effectively in his early chapters. But there is much besides 'creepiness' in the book: cheery descriptions of old-fashioned medical-student life, an excellent 'interior' of a common lodging-house, a well-sustained tracking of a mystery, and much of the soft Suffolk talk by one who evidently knows it well. This single-volume story is one which should be asked for at Mudie's."—*The World.*

"Charley Kingston has one of the most startling experiences ever accorded to a medical student. This incident is placed in the foreground of the story where the clever French mystery novelists put the murder. The manner of telling the tale reminds one a little of that of Mr. William Gilbert, who used to write such realistic and powerful stories. This is in our opinion a favourable and flattering criticism."—*Daily News.*

MACMILLAN & CO., LONDON.

NEW VOLUME IN THE

INTERNATIONAL SCIENTIFIC SERIES.

JELLY FISH, STAR FISH, AND SEA URCHINS.

BEING A RESEARCH ON PRIMITIVE NERVOUS SYSTEMS.

By G. J. ROMANES, LL.D., F.R.S.,
Author of "Mental Evolution in Animals," &c.

Crown 8vo. Cloth. 5*s*.

London: KEGAN PAUL, TRENCH & CO.

SECOND EDITION, now ready at all Libraries and Booksellers'. One Volume. Demy 8vo, with Two Maps and numerous Full-page and smaller Woodcut Illustrations. Price One Guinea.

THROUGH MASAI LAND:

A Journey of Exploration among the Snowclad Volcanic Mountains and Strange Tribes of Eastern Equatorial Africa.

Being the Narrative of the Royal Geographical Society's Expedition to Mount Kenia and Lake Victoria Nyanza, 1883, 1884.

By JOSEPH THOMSON, F.R.G.S., Leader of the Expedition, Author of "To the Central African Lakes and Back."

From the *Times*.—"It would indeed be difficult to find another man who could have gone through what Mr. Thomson has done, and have come out of it alive and with stainless hands. Mr. Thomson has been able to open up and shed broad daylight on a region previously absolutely unknown. . . . Altogether he has done a solid piece of work of unusual scientific value."

London: SAMPSON LOW, MARSTON, & CO., 188, Fleet Street, E.C.

C. D. AHRENS,

PRISM WORKER AND PRACTICAL OPTICIAN,

Spottiswoode, Esq., P.R.S., &c., &c., and for Frank Crisp, Esq., LL.B., B.A., &c., &c.

TRADE SUPPLIED WITH PRISMS.

NOW READY, Large Post 8vo, with 15 Maps and 60 Illustrations, Cloth gilt, price 21*s*.

EUROPE,

By F. W. RUDLER, F.G.S., and G. G. CHISHOLM, B.Sc. Edited by SIR ANDREW C. RAMSAY, LL.D., F.R.S. With Ethnological Appendix by Professor A. H. KEANE, M.A.I.

Forming the Concluding Volume of STANFORD'S COMPENDIUM OF GEOGRAPHY AND TRAVEL for General Reading, a Series of Volumes descriptive of the Great Division of the Globe.

NOTE.

This volume on "Europe" is based, like the others of the Series, on Hellwald's well-known "Die Erde und ihre Völker;" but it has been found desirable to recast a great part of the original work. The labour necessary being more than Sir A. C. Ramsay could conveniently bestow on it, it was handed to Mr. Rudler and Mr. Chisholm. Sir Andrew, however, corrected the proofs of the entire translation and made extensive additions to the work, adding entire chapters on the subjects in which he was specially interested. By the recasting, the plan of the volume has been rendered much more systematic, and a large portion of the Physical part has been rewritten.

A valuable Essay on European Ethnology and Philology has been contributed, in the shape of an Appendix, by Prof. Keane. Throughout the work great care has been taken to insure accuracy, and to present the latest additions to our knowledge of the various subjects under discussion. Equal care has been taken in the preparation of the series of maps, which will, it is hoped, be found valuable accompaniments to the text.

London: EDWARD STANFORD, 55, Charing Cross, S.W.

This Day, 2nd Edition, Cloth, 352 Pages, Price 7*s*. 6*d*.

NATURE'S HYGIENE:

A SYSTEMATIC MANUAL OF NATURAL HYGIENE.

TWO DOORS FROM CHANCERY LANE. ESTABLISHED 1837.

THE "EXCELSIOR"
PATENT SPRING MATTRESS. AWARDS: TEN PRIZE MEDALS, FOURTEEN CERTIFICATES OF MERIT

The principle of arrangement permits the free movement of one sleeper without inconvenience to the other, admits of complete isolation of each, and *effectually prevents depression in the centre.*

THE "Excelsior" AND "Matlock" BED-RESTS.

THE "EXCELSIOR" & "MATLOCK" COUCHES.

Retail from Cabinet Makers, Upholsterers, &c.

THE NEW PATENT
WOVEN WIRE MATTRESS.

The leading peculiarity of this Mattress is the unique combination of a woven wire central portion with helical springs of great strength and reliable temper, giving advantages possessed by no other make. The helical springs obviate the tendency in all woven wire mattresses to become hollow and so cause sleepers to roll into the middle of the bed.

THE CELEBRATED

Is unrivalled for Gardeners', Foresters', Farmers', Joiners', and Amateurs use. It requires no oil. Sharpen with a spittle or water. Puts on a keen, sharp edge; no humbug about this. Has stood the test of 100 years. Cut in Hones for Axes, Hedge Knives, Razors, Penknives, and Plane Irons, &c. Honourable Mention, Paris Exhibition, 1878; and Bronze Medal, London International Exhibition, 1884. Ask your Ironmonger or other retail house to get you one, and give my address; if he won't, drop me a note.

JOHN C. MONTGOMERIE,

Tam O'Shanter Stone Hone Works, Dalmore, Tarbolton Station, R.S.O. Ayrshire.

FERNS, A SPECIALITY.

The largest and most profusely ILLUSTRATED CATALOGUE of FERNS ever published, containing much valuable information, many Synonyms, numerous Descriptions, and copious yet simple "Hints on Fern Culture"; representative of our IMMENSE STOCK of FERNS, which is probably the largest in the World, suitable for STOVE and GREENHOUSE cultivation, for OUTDOOR FERNERIES, and other purposes.

May be had on application. PRICE 1s.

ABRIDGED CATALOGUE OF OVER 1000 SPECIES AND VARIETIES POST FREE.

FERN NURSERY, SALE, MANCHESTER.

FRY'S COCOA

GOLD MEDAL, CALCUTTA, 1884.

"Pure Cocoa."—CHAS A CAMERON, Analyst for Dublin.

"Strictly pure, easily assimilated."—W. W. STODDART, Analyst for Bristol.

EXTRACT

Nineteen Prize Medals Awarded.

HOLLOWAY'S PILLS

THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1000 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being **£333,383**.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

PAPERS, ETC., BY THE LATE DR. LAUDER LINDSAY.

...ATION

...ctive root of evil—not an unmixed ...ence [illegible] an absolute perfect race ...ould these absolute natures and the ...ly conditions have produced ...ations which can supply a steady ...ly to the most versatile engineer, ...there not present great [illegible]

...ntrary, of the experience of ...ne of the leaders of ...ed. The wide diversity ...ed, [illegible] ...ed, [illegible] ...ed, [illegible]

in the face. Similarly, the average politician and the ordinary elector, having but little knowledge of philosophical experiments, or faith in them, will probably not believe in their great practical value until national distress and panic legislation ensue. The love of money also, and the desire of acquiring it quickly without commensurate sacrifice, fostered by our having so easily obtained it by means of our coal and science, is so strong in this nation, that probably nothing but the actual loss of wealth in the form of diminished value of properties, will induce capitalists and land-owners to perceive and examine the scientific basis of their incomes. When, however, the stern reality of gradually increasing scarcity of coal, and consequent inability to pay for our great supplies of foreign food by means of that coal, and of articles produced by its aid, comes upon us, perhaps the statesmen and wealthy classes of this country will see the indispensable necessity of new scientific knowledge, and be more ready to promote experimental research, with a conviction that its practical results are vast, though not always direct or immediate. G. GORE

MAMMALIAN DESCENT

On Mammalian Descent; the Hunterian Lectures for 1884. By W. Kitchen Parker, F.R.S. (London: Griffin and Co., 1885.)

AS far as we are aware, no attempt has hitherto been made to popularise in any detail the science of comparative embryology. It is therefore indicative of the characteristic originality of Prof. Parker that, on delivering a course of Hunterian lectures upon the embryology of the Mammalia, he should have aimed at charming a popular audience as well as at instructing a scientific one. We confess that upon reading the first paragraphs of his preface, in which he states his intention of handling his subject in a popular way, we felt apprehensive that, like sundry other lecturers with a similar aim and with subjects better suited to the killing of two birds with one stone, he was preparing for himself the misfortune of missing both his marks. But we had not got far into the first lecture without finding that our lecturer very well knew what he was about: he is provided with a double-shotted weapon of the most modern construction, and takes a genuine glee in knocking over some antediluvian toothbearing bird on the one side, and the sentimental scruples of a nineteenth-century audience upon the other. And this is done with so much of the vigour of enthusiastic science, as well as the genuine feeling of what we may term unspoiled poetry, that we feel our thanks are due to Miss Arabella Buckley who, it seems, first persuaded Prof. Parker to adopt this delightful method of writing. Moreover, it is obviously to him a natural method. We can everywhere see that he is now writing in the lines of his habitual thinking. The smallest details of his science catch a living glow from the ardour of his imagination, and as this imagination is everywhere charged with biblical thoughts and biblical metaphors, we are led by the force of example to compare it to some quickening spirit which makes all the dry bones of the skulls and skeletons stand up around him as an exceeding great army. Well it is for the cause of evolution that in Prof. Parker it has not only so indefatigable a worker, but likewise so elevated a preacher; and being thus as strong a champion on the side of sentiment as he is on that of science, we have only to congratulate him upon the wisdom of adopting Miss Buckley's advice, and appearing in the lists armed with the weapons of feeling as effectually as with those of fact.

The course consists of nine lectures, and there are, besides, extensive addenda. In the 229 pages to which the book runs, we have presented an excellent epitome of the author's work on the embryology of the Mammalia. The perusal of this epitome cannot fail to strike us anew with admiration at the prodigious amount of his labours, and the great results which they have accomplished. When future generations come to survey the work done by the contemporaries of Charles Darwin in establishing the doctrine of evolution, and in beginning the great task of tracing out the main lines of descent in the animal kingdom, the name of Parker will stand out as one of the most conspicuous of the landmarks.

Two or three quotations from the present volume will serve to convey a general idea of the style, upon which we have laid so much stress. Speaking of a remarkable proboscidian Insectivore, about the size of a rat (*Rhynchocyon cernei*), a ripe embryo of which he has obtained from near Zanzibar, the lecturer says:—

"I have, at present, merely worked out the skull of this valued specimen, but it has rewarded and delighted me more than any kind I have received for a long time past. If nature had titurated together the germs of four or five types of mammals, and had then made this mixture grow, she could scarcely have developed a more curious and composite creature than this long-nosed Insectivore. When Prof. Huxley propounded his oft-quoted theory of the evolution of the Mammalia, he might have known the structure and development of this type by inward sight. Nothing of the kind, however, is ever revealed to biologists in this manner, we only get our facts by opening out the fine folds of organic forms with needle and scissors; we do unroll a good number of the small scrolls, but it is painful and patient work. I am satisfied that no searcher after the evidences of evolution ever saw anything more instructive than what I have found in this small beast. I will make a catalogue of its characters. . . . Thus this greatly specialised kind of Insectivore, whilst retaining the most marked characteristics of the Metatherian skull, takes on two characters, one of which, had it become dominant, would have landed it amongst the Proboscidea, or elephants, whilst the other would have made it a Carnivore. It attempted too much at once, and thus, like a man in doubt, it made but little progress; moreover, in this developmental shilly-shallying, it failed to drop the Marsupial, to take on the new Eutherian, nature, and was thus in danger of going out of being with many of the members of that much-extinguished type. Other types, not thus confused in their ambition, worked out the old strain of Metatherian degradation, and, taking to one definite line of ascent, put on new specialisations in harmony with their surroundings, and to this day their descendants are the rulers of the forest and the field."

Again:—

"Supposing the theory of the slow secular transformation of the old general types into new special types to be true, then the existing mole, in its perfection of adaptive structure, has been as long in coming to its present perfection as the larger and nobler prone or erect types that trample the earth over its head. In its own line, doing its own dark work, it is as complete a creature as the clear-eyed, super-terrestrial types; as a mole, it is true

summate—a complete and perfect example of a subterranean tyrant; all around him are hosts of juicy grubs and worms, and thereout sucks he no small advantage. Concerning tastes there is no disputing: one naturalist is fond of whales, another of moles, shrews, and mice. All these amusing types must have their supply of food; the great mother, Nature, loves all, and shakes out of her lap plenty for every kind. When we reflect that our country possesses about 1200 species of insects, and that some of the species are prolific beyond all calculation, then we come to understand how the higher insectivorous tribes—birds or small mammals—find so plentiful a table in the wilderness. The hungry, impatient cat, who mistakes a shrew for a mouse, and then leaves her musky prey untasted, would starve upon that which fattens the mole, the shrew, or the bat. The last of these kinds hawks for his small prey, but the shrew, with his delicate proboscis, his sharp eyes, and his quick ears, knows where small beetles most do congregate. These he crunches and munches with exquisite teeth, the cusps or points of which are of a deep ferruginous red colour, more beautiful, strange to say, because they are thus stained. The Power that made the beetle strong in his polished and enamelled armour made also the teeth of the shrew most fit instruments for crushing that armour in which the beetle trusts. It is pleasanter to look upon this vacillation, so to speak, of beneficent purpose from the stand-point of a Darwin than from the stand-point of a Paley; there is much that is painfully mysterious in the whole matter, and we only see it in a partial view."

The lectures concludes thus:—

"When the eyes of the prophet's servant were opened he saw no longer barren rocks with mist resting upon them, but the whole mountain was full of chariots of fire and horses of fire. The vestments and ritual of nature may take up all the attention and use up all the energies of her votaries; these superficial observers fail, however, to find the real religion of nature—the beautiful but awful omnipresence which every flower and every insect reveals. The phenomena of nature are all mere fading pageants, and the really cultivated mind finds lasting satisfaction in meditating upon the recognisable forces that underlie all sensible phenomena.

"This, however, is what the older philosophers called 'dry light,' and is not comfortable to most minds. The deeper things of nature are a sort of manna, but the souls of some people become dried up if you give them merely this celestial kind of diet; so that they murmur and say, 'We remember the fish which we did eat in Egypt, freely; the cucumbers, and the melons, and the leeks, and the onions, and the garlic.'

"And yet this ignorance of nature is set up as a dead wall against all progress of thought; for these people are 'most ignorant of what they're most assured,' certain that they know all about their 'glassy essence'; and, although as blind as moles, they are the enemies of all who have had their eyes opened, to whom the mountain is no longer misty and dark, but flaming with light.

"'Ne sutor supra crepidam'—do not trust the cobbler in things outside his calling—is a proverb that cuts both ways. The biologist may surely be allowed to know things that relate to his own calling: the man who never dreams of life, and the science of life, should be careful how he contradicts its experts. On the other hand, bigotry is not confined to one class of controversialists; some very bitter things have been said by men against faith whose culture and science ought to have taught them better. We have a right to look for nothing but 'sweetness and light' from the apostles and prophets of this new dispensation.

"When the dust of controversy shall have subsided, when those who have to receive new ideas as if by a surgical operation begin to feel the stirrings of these new conceptions thus let into them—the new heaven of nobler thoughts about nature, and of the great First Cause of nature—then all who can think will find that they are colonising a new Atlantis.

"The old song of the creation puts it thus—Evening was—morning was—day one.

"Thus the shadows of the evening came first, and the rosy light of dawn afterwards. Now, in science, even in biological science, the morning is spread upon the mountains, and soaring birds are singing at heaven's gate; so that the drowsiest folk are beginning to stir themselves ere well awake."

We have selected these examples for quotation in order to recommend the book to the class of readers for whom it is primarily intended; but we must not conclude without again observing that the lectures contain so much solid information of the strictly scientific kind, that even the most bigoted of biological experts cannot afford to disregard the material mountain, however little heed they may care to give to the vision of the fiery chariots.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

Civilisation and Eyesight

IN reading Lord Rayleigh's interesting remarks in NATURE (p. 340) upon Mr. Carter's paper, it has occurred to me that we should not, in considering the question of "aperture," entirely omit the fact that this, though probably following a general rule applicable alike to savages and civilised beings, varies in individual cases. An assistant, who has recently left my observatory, had a singularly "sharp" eye, and could pick up with ease companions to double stars, small satellites, &c., which others saw with difficulty. Such were his powers in this respect that I always appealed to him in the case of a doubtful observation. I noticed one day how large the pupils of his eyes were, so large that I asked him if he had taken anything to artificially dilate them. Subsequent examination proved that they were, though of course varying with the stimulus of light, always much larger than those of most other persons, so much so that I laughingly used to call them "cat's eyes." They had also, in fact, a peculiarity, attributed to feline sight, that he could read fine print and distinguish lines by a light much less bright than I could, and habitually used the gas half turned on, &c. Probably such instances would not be rare if they were looked for. Another question arises on this head: Could it be possible that such a condition of the eye, natural in some persons, could, by certain uses of the member, be fostered in others?

I should not have ventured the suggestion but for having read of the "chamois" eye, by which the habitual, or even casual, Alpine hunter can be recognised. I have no references at hand, and it may be it was the look, and not the eye itself, that gave rise to the cognomen; but if there was any change in the eye-conditions, and especially in that of aperture, we might find a reason why the far-gazing savage improves the power of the eye by use. We know that by certain trades—watch-making, for instance—these conditions are varied adversely to long sight, and in the case of sailors and preventive service men a contrary effect seems induced. Lord Rayleigh thinks that the superiority of the savage is only a question of attention and interpretation of minute details, but when one reads that two distant dots are resolved into distinctly-appreciable personages as regards sex, garments, &c., one begins to suspect that "aperture" must also come into play. At all events an inquiry whether these far-seeing savages have large eye-apertures might help the solution of the matter.

The peculiarity affecting my assistant's eyes may be more

common with the savages then with us, or may have been specially prominent in those selected for experiment.

Coldown, February 16 J. RAND CAPRON

Erosion of Glass

SOME time in the end of 1882 Surgeon-Major Biden, writing from Madras, related in NATURE that certain glass vases on which white-ant mud had been deposited had been eroded over the area of deposit in such a way as to suggest that an acid having, like hydrofluoric acid, a power of dissolving glass, was present in the "mud." On reading this I was reminded of the observations of my teacher, Mr. George Rainey, recently deceased.

Mr. Rainey, in the course of his observations on molecular coalescence, had shown that when carbonate of lime was deposited in spherical forms on the surface of a glass slide in the presence of a strong solution of gum, the glass was eroded at every point of contact of a sphere. He explained the phenomenon, as I believe rightly, by the principle of molecular coalescence. In the embrace of the colloid gum, the molecules of the glass adjoining the spheres were drawn into the spheres, and a little cup corresponded to each sphere-contact. There was certainly no question of the action of an acid, the solutions used being distinctly alkaline.

Inspection of the bottles in which the substances have been kept will show that carbonate of lime, moist or dry, carbonate of potash, moist or dry, chloride of calcium, moist or dry, do not in the absence of colloids erode glass. It appeared to me probable that the white-ant mud must consist of a mixture of some colloid with carbonate of lime or some other salt capable of taking spherical form. I wrote to Surgeon-Major Biden stating the possibility as it appeared to me, and suggesting that the mud should be examined as regarded colloid and earthy matter. He replied most courteously that the mud was not at the time to be obtained, but sent some of the earth which formed its basis.

Experimenting with this earth alone, I was not able to etch glass. But in view of some interesting speculations which this episode started for me, I have since made some experiments directly bearing on the possibility of the erosion of glass surfaces by saline matters of alkaline reaction deposited on them within a colloid bed or matrix.

I inclose for your inspection a glass slide which has been so treated. More than a year ago this slide was coated with a layer of paraffin, melted on. The word "ANT" was drawn on the side with a wood point, in the expectation that etching might be effected where the paraffin was removed, the wood point being incapable of scratching the glass. The expectation was not entirely fulfilled. The paraffin, not being sticky enough, scaled off in sheets so as to leave the whole surface ultimately exposed. This whole surface is now seen to be etched. At first sight the glass looks as if it were covered with a semi-opaque deposit. But it has been boiled in hydrochloric acid and in water, without any change becoming evident, and under the microscope the appearance rendered is clearly an appearance of erosion.

The details of the experiment were as follows: a strong solution of gum arabic in distilled water was made and filtered. It was divided into two portions. To one was added a small quantity of chloride of calcium, to the other a small quantity of carbonate of potash. A wide-mouthed bottle, three inches in height, was half filled with the first solution, and the second solution was slowly poured on the top of the first, so as to avoid mixture of the two. The slide, prepared, as already described, was placed vertically in the bottle, so that the middle region of the slide corresponded to the level of the meeting of the two solutions.

The slide was found, at the end of a twelvemonth, denuded of its paraffin, and coated with an incrustation of carbonate of lime most dense at and near the meeting level of the two solutions.

Under the microscope the surface of the slide presents many kinds of erosion—spherical, linear, and intermediate. But in proportion as higher and higher objectives are used, all the appearances are shown to be of circular form, the lines, for instance, being resolved into lines of circular pits.

I dare not make this letter too long, and therefore include in it only so much as bears on Surgeon-Major Biden's most interesting communication. It suffices, at the moment, to indicate that the surface of a glass slide may be eroded in a way to suggest the action of an acid, such as hydrofluoric acid, when no free acid is present; and that erosion may occur when the glass is brought in contact with alkaline fluid, a colloid, a crystalline substances capable of assuming, in the presence of a colloid, spheroidal forms.

I propose to state the results of this and other experiments, and some speculations suggested thereby, before the Royal Microscopical Society.

WILLIAM M. ORD

7, Brook Street, W.

Echium Crossing

THE gardens of Madeira are remarkable for the neglect of native plants. This is due in part to indigenous indifference, and also to a preference for familiar forms amongst people who migrate hither from various regions, though chiefly to the temptation to test the facilities of growth and naturalisation in a moist and equable sub-tropical climate. Hence it is often easier to import species peculiar to Madeira than to find them in their native place; but none the less do these rocks abound with conspicuous examples of interesting genera.

I have cultivated for many years two large echiums upon the terraces of the Luinta do Valle, 300 feet above the sea, namely, *E. fastuosum*, the Madeiran littoral species, a perennial shrub 3 or 4 feet high, with hairy light green leaves and branching stems crowded with scorpioid racimes of light-blue flowers with white stamens. And secondly, *E. simplex*, the giant Canarian species maturing in Madeira in the second year. This remarkable plant has large, smooth, silvery leaves, and terminates its growth in one unbranched stem densely packed with folded flower-stalks bearing pure white blossoms, and forming a pyramid reaching sometimes 14 feet in height. *E. simplex* dies after flowering. The flowers in both species last from three to five weeks, and the unfolded flower-stalks measure 2 to 3 inches in length.

Until 1882 the two echiums, though growing together and having their scentless flowers freely visited by bees and insects for their abundant nectar, had remained distinct; but, in 1882, after introducing a swarm of Ligurian bees from England, I found that a cross-fertilisation had been effected, which has left me very few examples of *E. simplex*.

The hybrid Echium possesses the leaves of the giant plant, and the stem merely bifurcates or branches sparingly. The flowers are tinged light blue, and the perennial habit of *E. fastuosum* is expressed by a continual growth of the flower racimes, which, after flowering for two years, measure 36 inches in length, and are still unfolding. The seeds of this hybrid have not germinated.

I am now preparing to effect a cross between *E. simplex* and the handsome mountain *E. candicans* of this island at my country residence, 2000 feet above the sea.

E. candicans and *E. fastuosum* have frequently blended, producing plants less new in structure than in habit; but such hybrids have been quickly lost, either in sterility or reversion.

Madeira, January 26 MICHAEL GRABHAM

[This is an interesting case of the spontaneous appearance of a hybrid between two very distinct species. The occurrence of such hybrids is frequent in some genera, such as *Verbascum* and *Primula*, and gives systematic botanists much trouble. There is a striking picture of *Echium simplex* at Teneriffe, in the North Gallery at Kew, No. 23.—ED.]

The Irideacent Clouds

THE coloured fringes and bows described by Mr. N. in Prof. C. Piazzi Smyth's communication (p. 316) are clearly of a totally different character from the iridescent clouds that were so widely remarked in December. I take the "fringes and bows in circles" mentioned by him to be simply the same phenomenon of coloured circles that is so often seen around the moon, which goes by the name of a "corona"; and the reason why it is not easily seen around the sun, except by reflection in glass or water, is that the sun is too dazzling to look at directly. There is another phenomenon of coloured clouds which is probably also alluded to by Mr. N., and that is when thin clouds, usually cirrus, show interference colours, often very vividly; the positions of these colours evidently depending on the structure of the clouds, and being quite irregular with reference to the sun. The iridescent clouds recently observed no doubt owe their colour to the same cause, but the kind of cloud was evidently different, and the colours produced were much more striking. The clouds themselves were quite recognisable as

being of a peculiar type, even when too far from the sun to show any colour. The clouds thus coloured are usually of a much striated or rippled structure, and show the colours generally in small spectra; whereas the clouds seen in December were remarkably smooth in texture, and although often striated, the striations were feeble and comparatively few, and in straight lines, while each cloud showed one regular gradation of colour.

Whether the coloured clouds described by your correspondents, with the exception of those mentioned by Mr. N., were all of the same kind, it is difficult to decide; perhaps they may have been so, in spite of the varieties in their appearance. Some observers describe the body of these clouds as having been dark, in particular your correspondents at Darlington and Broseley (Shropshire), pp. 192, 193, whereas all seen here were white or bright. Still, those clouds seen further south were probably of the same kind, only thicker. The difference in shape is most likely not a radical one, as the larger clouds seen here had wavy, not straight, edges, though their general directions were the same as the sides of the more rectangular ones. The nearest approach here to a pallium of these singular clouds was on the morning of December 12, when there occurred, at 8.15 a.m., an extensive pale steel blue film above the region where the sun was, and reaching to an altitude of 25°.

Dr. H. Geelmuyden, observing at Christiania on December 8 (see p. 264), appears to place the peculiar clouds at a lower level than cirro-cumulus, but as seen here they were always the highest clouds.

In conclusion, I think that Prof. A. S. Herschel is mistaken in supposing these clouds have been "only a good instance of a common sight," but although I never noticed them before, I do not dispute the suggestion of Dr. Geelmuyden that they may be seen more frequently than some of us have thought. I have not seen them since December 13. T. W. BACKHOUSE

Sunderland, February 11

Human Hibernation

I DID not answer your correspondent's query on human hibernation in your issue of the 5th inst. (p. 316), because I thought some one better informed than myself would answer it. However, as no one has done so, I may as well give a solution of this well-known Indian trick which I have seen, but the authority for which, I am sorry to say, I cannot remember. It is very simple, like all these things are when you "know how they are done." A tunnel is dug from the grave to the neighbouring jungle; the grave itself is partly prepared. The subject is then, in sight of the spectators, prepared, by having his ears and nostrils filled with wax, and his tongue turned back. He is then apparently buried, creeps through the tunnel, and gets away. After six months, or any other interval, he creeps back again, is dug up apparently lifeless, and restored with infinite pains. In some cases, I believe, a sentry has been placed over the grave, but, of course, without results

An Error in Ganot's "Physics"

I BEG to call attention to a typical error in a formula which appears to have run through ten editions of Ganot's well-known treatise. It is one not difficult of discovery by that somewhat too rare class of students who carefully plod through all the steps which lead up to it, but very likely to be overlooked by the more common class who are content to extract the formula as it stands with the undoubting faith reasonably based on "Tenth Edition, revised and enlarged."

The formula which represents the weight of air saturated with vapour occurs on p. 325 of the tenth edition, and is printed—

$$P = \frac{0{\cdot}31 \times V.F}{(1 + \alpha t)\,760}\,(H - \tfrac{5}{8}F).$$

The first F should obviously be expunged.

E. DOUGLAS ARCHIBALD

[illegible] Wells, February 16

[illegible] on Clouds

[illegible] phenomenon is at all common, [illegible] and that it might

Whilst at anchor in Cumberland Bay in the Island of Juan Fernandez on the evening of December 24, 1884, we observed the following remarkable sight. The Bay is situated on the north side of the island, and some way inland is a remarkable hill, called the "Yunkua," or "anvil," it being somewhat of the shape of one; it is the highest hill in the place, viz. 3005 feet, and from the anchorage bears about south-west, and is distant two miles. The Bay is closed in by high cliffs and hills. On the day mentioned, shortly after the sun had disappeared behind the western hills, we observed this hill make a distinct shadow on the clouds above it, in which every irregularity and peak came out with wonderful clearness. The shadow lasted till about 30″ before the time of sunset (which was invisible to us), and was inverted and inclined to the hill as in a mirage at about 30°. The weather at the time was very fine. Barometer, 30·22; temperature of altitude thermometer, F. 62°; and very few clouds were about. ALFRED H. TARLETON

H.M.S. *Constance*, at Sea, January 25

THE METEOROLOGY OF HAVANA[1]

THIS annual of the Royal College of the Society of Jesus at Havana for 1875, which has just been published, possesses more than a passing interest. The observations were made daily every two hours from 4 a.m. to 10 p.m., and include pressure, temperature, humidity, wind, rain, magnetic, electric, optical, and other weather phenomena. The results are plotted on large monthly diagrams, and as each day has six-tenths of an inch devoted to it, the two-hourly observations of all the different elements can be readily seen and compared with each other; and this part of the work is done with a scrupulous care and accuracy it would not be easy to surpass. On the same diagrams are marked the days on which auroras are reported to have been observed in the United States, as published in the *Monthly Weather Review* at Washington.

A note is appended to each month's observations, drawing attention to the more significant of the magnetic perturbations in their relations to the changes of weather at the time, and in particular to the "nortes," or "northers," of the cooler months of the year. Thus, on April 3, 4, and 5 a "norther" prevailed, which was succeeded on the three following days by a remarkable magnetic perturbation, which was accompanied with a high barometer and a strong wind, rising in the afternoons to a rate of 35 kilometres per hour, with daily manifestations of aurora in the United States, but was unaccompanied throughout with any electric phenomena. Again, the magnetic perturbation, of April 13 was coincident with a characteristic "norther," much thunder and lightning, a very heavy rainfall, and a disposition and state of the aqueous vapour which give rise to solar and lunar halos, and other optical effects; but during the time no auroras were reported from the United States. Father Viñes points out in the monthly notes various other relations between the magnetical and meteorological phenomena which suggest that this line of inquiry is likely to lead to valuable additions to our knowledge of weather changes.

The mean annual pressure at sea-level is 30·067 inches, the maximum being 30·129 inches in January and the minimum 30·002 inches in September, with a secondary maximum of 30·092 inches in July and minimum of 30·066 inches in April. As regards the diurnal oscillation from the morning maximum to the afternoon minimum, the greatest occurs in the winter months, when it amounts to 0·080 inch, whereas in July it is only 0·051 inch. These diurnal and seasonal fluctuations in their varying amounts have no small significance in their relations to the analogous phenomena in the United States and over the high pressure area of the Atlantic. The mean annual temperature is 77°·7, rising to the maximum 82°·2 in July, and falling to the minimum 73°·0 in December. The

[1] "Observaciones Magnéticas y Meteorólogicas del Real Colegio de Belen de la Compañia de Jesus en la Habana. Año de 1875." (Habana, 1884.)

absolutely highest temperature, 98°·8, occurred at 4 p.m. on July 30 under very striking circumstances. For four days previously auroras had been observed in the United States; the magnetic and electrical conditions showed marked disturbances at Havana; atmospheric pressure, which had been low, began to rise on the 30th, on which day, at 2 p.m., the relative humidity fell to 45, but rose four hours after to 84. The temperature, which at 4 p.m. was 93°·8, thereafter instantly and rapidly fell, and by 6 p.m had fallen to 78°·8. The lowest temperature for the year, 55°·9, occurred at 6 a.m. on December 16, at the termination of a "norther," which overspread the sky with cirri, attended with solar and lunar halos; and was immediately followed by a low barometer, remarkable hygrometric changes and irregularities in the direction and velocity of the wind.

Excepting a greater tendency to soothing during the warmer months, the wind varies little in direction from month to month. The diurnal variation is interesting. From 10 p.m. to 8 a.m. it is E. by S.; at 10 a.m. E. by N.; from 10 a.m. to 2 p.m. N.N.E.; 4 p.m. N.E.; 6 p.m. E.N.E.; and at 8 p.m. E., thus showing in a marked manner the influence of the sea breeze at Havana. The daily changes in the wind's velocity are very large. The minimum occurs from 4 to 6 a.m., and the maximum from noon to 4 p.m., the maximum velocity being four times greater than the minimum. The strongest winds occur in April, and the weakest in November; the winds in April blowing with double the velocity of those in November. As regards direction, the strongest winds are the sea winds which blow from N.N.E. and E., and the weakest the land-winds from E.S.E., S.E., and S.W., the former blowing with double the force of the latter.

The annual curve of thunderstorms is a very decided one. Of the eighty recorded during 1875, sixty-five occurred during the five months from May to September, and only three during the four months from January to March and December. The annual rainfall was 42·39 inches, about half of the whole amount falling in August and September, during which time 20·61 inches fell. Only a quarter of an inch fell in December, and half an inch in November. The total evaporation for the year was about 60 inches, the maximum, 6·92 inches, being in April, when the air is driest and the winds strongest, and the minimum 3·60 inches in September, October, and November, when the air is most highly saturated and the force of the wind least. As regards the occurrence of rain at different periods of the day, more than 50 per cent. of the whole hours during which rain is noted to have fallen were between noon and 6 p.m., thus closely associating the rainfall with the diurnal period of the thunderstorms. The almost total absence of the thunderstorm from the rains of the winter months, as compared with the summer months, when lightning, or some other electric phenomenon occurs almost daily, is an important feature in the climate of Havana from its bearing on the theory of the thunderstorm.

THE WHALE EXHIBITION IN HAMBURG

DURING the autumn of last year an exhibition of considerable novelty and interest to zoologists was held in Hamburg, embracing complete skeletons, parts, and craniæ of whales, products of the same, and apparatus used for catching these greatest organisms of the world from the earliest times to the present day.

The suggestion for this exhibition came from the writer of these lines, who offered to exhibit three of the greatest fin-whale skeletons in existence. Dr. H. Bolau, director of the Zoological Gardens in Hamburg, succeeded, in spite of many obstacles, in arranging this exhibition and collecting interesting and valuable material, towards which Prof. Pagenstecher, director of the Natural History Museum, also contributed greatly by arranging the exhibits and obtaining several rare specimens acquired by the German Expedition of 1882-83 to South Georgia. In this part were also some splendid water colour drawings from this island, executed by Herr Mc-laff, which were greatly admired.

The exhibition, which was divided into four parts, viz. one for the whale fauna, one for the hunting-gear, one for the whale products, and one historic-ethnographical, took place partly in the open, partly in a hall.

In the first section, naturally, the Cetaceæ, were most prominent, these monsters being mounted in the Garden. Of true Balænidæ, the Hamburg Zoological Museum exhibited a cranium of *Balæna mysticetus*, L., a very rare specimen. Otherwise the Balænopteridæ, or fin-whales, were most numerous, there being four different species of this family. The most imposing of them all was the skeleton of the "blue" whale (*Balænoptera sibbaldii*, Gray), the greatest animal on earth. It measured 75 feet in length, and was mounted in its natural position. The specimen seemed to have been full grown, as no division between the epiphyse and the vertebral body could be discovered. As an individual osteological curiosity may be mentioned that the jugal bone consisted of two bones, a smaller and a larger piece, which are closely united by strong ligaments.

Not far from this specimen stood the skeleton of the common fine-whale (*Balænoptera musculus*, Compan.), 63 feet long, which was, as Prof. Flower describes it, "in adolescent state." The greater part of the thoracic and lumbal vertebræ showed distinct separation between the epiphyses and the vertebral body, which was also the case with the limbs. Although the length between these two species is not so very great, there is a marked difference between their structure. The fine-whale is remarkable for its lightness and elegance; in proportion to its great length, some parts of the skeleton seem indeed quite fragile, whereas the blue whale shows throughout in its structure a massiveness bespeaking enormous muscular powers. The difference became even more striking when the fin-whale was compared with a third species, the *Megaptera boops*, O. Fabr. This skeleton was 54 feet long, and therefore a large individual, and was found dead at sea between the coast of Norway and Russia. From the complete development of the ossification and coalescence of epiphyses with the vertebral bodies and respective diaphyses of the extremities it was clearly a full-grown animal. It gave an impression of heaviness, on account of the short thick bones and the great length of the fore-limbs, 14 feet, which is very apparent. To this individual belonged the whale-bone complex, part of which was shown. Next the same a cranium of this species of whale was exhibited with a complete whale-bone complex. This was a very fine specimen, and was prepared for the Museum of Natural Sciences at Stuttgart, where it now is.

The above-mentioned skeletons and crania were prepared by me in 1883 at the whaling establishments at Vardö (lat. 70½° N.), but the three skeletons, which were I may be permitted to say, very complete and fine specimens, I had steamed and finished in Hamburg.

In the open, too, there was mounted a skeleton of *Balænoptera rostrata*, Fabr., the smallest of all fin-whales; but this specimen left much to be desired in the way of completeness and finish. It was, however, interesting by its history and age, and is perhaps the oldest Cetacea in any museum. For 200 years it has been instated in the town hall at Bremen, where there is an inscription on the wall to the effect that the animal stranded at Bremerhafen on May 9, 1669, whence it was brought to Bremen, and the skeleton accorded the above-mentioned honour.

As representative of the great "tooth" whales, there was the lower jaw of a spermaceti whale belonging to

individual which, in 1849, was taken at the Canary Islands.

Dr. Bolau had drawn some very interesting maps showing the habitat of the Greenland whale, the Antarctic whale, the blue, and the spermaceti whales, which were greatly admired.

One of the most valuable exhibits was, however, the cranium of a narwhale (*Monodon monoceros*, L.) with two tusks. It was brought to Hamburg from Greenland in 1684. There are, I believe, at present in Europe only a dozen such craniæ, among which the one exhibited here is certainly the oldest. The most remarkable feature about this cranium is, however, if the inscription attached can be relied on, that it is that of *a female*. The tusk is, as is generally known, never developed in the females. The description is accompanied by a drawing of the whale and a young one, stated to be the offspring of the former. It is, nevertheless, hardly possible to accept this statement, at variance with all experience.

In addition to tusks of narwhals, skeletons and stuffed specimens of other kinds of tooth-whales were exhibited, as, for instance, of *Orca gladiator*, *Delphinus delphis*, *Phocæna communis*, *D. tursio*, and a cranium of bottle-nose *Hyperoodon latifrons*, Gray, which, according to the latest researches, is only the male of *H. diodon*.

Of the fœtus exhibited I may mention those of *Balænoptera rostrata*, Fabr., *Rhinodelphis leucoplevrus*, Rasch., and one of *Megaptera boops*, Fabr., only 12 inches long, exhibited by the writer.

Besides the exhibits belonging to the order of Cetaceæ, there were some fine specimens of *Sirenia*, as *Manatus* and *Halicore*, skeletons as well as stuffed animals, exhibited by the University of Kiel. There were, further, a fine collection of seals, of which I shall, however, only mention *Otaria Godeffroy*, from the coast of Peru. As some of the greatest curiosities, should be added, a perfect stuffed specimen of the sea-elephant, 11 feet long, and two sea-leopards from South Georgia.

The exhibition was visited by a considerable number of zoologists, and may, in every respect, be said to have been a success.

G. A. GULDBERG

The Zootomical Museum, Christiania

CHESTER NEW MUSEUM

THE foundation-stone of this museum was laid on February 5 by the Duke of Westminster, K.G. We have previously referred to the work done by the Chester Natural Science Society, and the Archæological Society, whose joint museum is now to be placed in a permanent building, uniting under one roof accommodation for it, an art gallery, and every provision for Science and Art Department classes. The remains of ancient Chester, which came to light from time, found their way to the British Museum up to the year 1849, when the Rev. W. H. Massie, the Rector of St. Mary's-on-the-Hill, called a meeting to consider the formation of a museum, and a society was formed for "the illustration and preservation of the remains of antiquity and other objects of interest in the city and in the county." The Society's "collection" was first housed in a cupboard at the Commercial Buildings; thence it was removed, first, to the Episcopal Palace in Abbey Square, afterwards to a house in Lower Bridge Road, to join the Museum of the Natural Science Society, whose collections are of considerable extent and essentially local in character, thanks to the marked love of nature and zeal for scientific research infused into many of the Chester citizens by the founder of the Society, the late Canon Kingsley, and the admirable rules for directing local investigation by which the Society is governed. Under the presidency of Prof. McKenny Hughes, the Society remains as vigorous as ever, as is the Archæological Society under that of Dean Howson, who, since the failing health of Mr. Thomas Hughes, F.S.A., to whom great credit is due, has taken an active interest in the Society, and in 1882 became the chairman of a joint committee to secure a building to answer all the requirements of science and art in Chester. This Committee selected a site in the Grosvenor Road, the greater part of which was at once placed at their disposal by the Duke of Westminster, who, moreover, headed the subscription list with the munificent sum of 4000*l.*, to which the Committee have since received promises of sums amounting to a further 3500*l.*

The architect is Mr. Thos. M. Lockwood, of Chester; the tender for the erection of the work accepted by the Committee is for 8150*l.* The elevation of the building, with its octagonal turret, with lantern surmounted by a quaint ogee roof, surmounting a steep-pitched roof, suggests the municipal architecture of Holland. The joint library and reading room is 21 feet by 19; the natura history museum is 36 feet by 25; the lecture theatre 44½ feet by 30; the art and archæological gallery is 60 feet by 23; on the first floor are science class rooms; on the second those for art. Space is reserved for future extensions in all departments.

Prof. McKenny Hughes stated the object of the Museum to be three-fold, being "intended for teaching, for study, and for exhibition. We have long carried on teaching in this old city in connection with the societies which have for their object the study of natural science, but that is to be extended. We have already extended it by putting ourselves in connection with the teaching powers of South Kensington, and now we will bring this into shape and have class-rooms and teachers definitely appointed to carry on the work which has been so nobly taken up by your citizens. The Duke has mentioned already that he felt that a great deal of the work had been done by the enterprise of the citizens. Well, that is the work which we intend to carry on in the teaching departments of this institution; but it is also intended for study. The world is going on fast in the direction of knowledge. Every one is trying to acquire knowledge which shall be turned to money, or which shall be pursued for its own sake, or which will add to the comfort of the community. In all these directions we hope to assist. Men may come in here and study in the library, or in the laboratories, or in the museum."

At the subsequent dinner the chairman, the Dean of Chester, stated that Canon Kingsley gave impulse to the study of natural history in this place, which has by no means lost its momentum. What the Duke of Westminster has said concerning the deep interest taken today in scientific subjects is most strictly in harmony with the facts of the case. There is here, deeply-rooted in the minds of many, a determined love for science of this kind, which is the best possible augury for benefits to result from our museum.

Sir Philip Cunliffe Owen, K.C.M.G., C.B., responding for art, said, "this is a museum after my own heart, for I think it corresponds entirely with what was in the mipd of the Prince Consort when he established the Science and Art Department and the South Kensington Museum. It was a part and parcel of his scheme that the teaching and the examples should be under one roof, and it has been found that the example of the Science and Art Department, combined as it is with one of the finest art museums in the world, and combined as it will be, I hope, in the near future with one of the finest science museums that may be created, has done more good, not only in this country, but throughout the world, than anything else which had been thought of before. When we think of the museums of the past, we know that they could not speak for themselves; they were examples, but however interesting and however ancient they might have been, they had no speaking powers, because they were not in combination with a teaching organisation."

CHAS. E. DE RANCE

THE CLASSIFICATION OF THE VARIETIES OF THE HUMAN SPECIES.[1]

THE most ordinary observation is sufficient to demonstrate the fact that certain groups of men are strongly marked from others by definite characters common to all members of the group, and transmitted regularly to their descendants by the laws of inheritance. The Chinaman and the Negro, the native of Patagonia and the Andaman Islander, are as distinct from each other structurally as are many of the so-called species of any natural group of animals. Indeed it may be said with truth that their differences are greater than those which mark the groups called genera by many naturalists of the present day. Nevertheless, the difficulty of parcelling out all the individuals composing the human species into certain definite groups, and of saying of each man that he belongs to one or other of such groups is insuperable. No such classification has ever, or indeed, can ever, be obtained. There is not one of the most characteristic, most extreme forms, like those I have just named, from which transitions cannot be traced by almost imperceptible gradations to any of the other equally characteristic, equally extreme, forms. Indeed, a large proportion of mankind is made up, not of extreme or typical, but of more or less generalised or intermediate, forms, the relative numbers of which are continually increasing, as the long-existing isolation of nations and races breaks down under the ever-extending intercommunication characteristic of the period in which we dwell.

The difficulties of framing a natural classification of man, or one which really represents the relationship of the various minor groups to each other, are well exemplified by a study of the numerous attempts which have been made from the time of Linnæus and Blumenbach onwards. Even in the first step of establishing certain primary groups of equivalent rank there has been no accord. The number of such groups has been most variously estimated by different writers from two up to sixty, or more, although it is important to note that there has always been a tendency to revert to the four primitive types sketched out by Linnæus, the European, Asiatic, African, and American, expanded into five by Blumenbach by the addition of the Malay, and reduced by Cuvier to three by the suppression of the two last. After a perfectly independent study of the subject, extending over many years, I cannot resist the conclusion, so often arrived at by various anthropologists, and so often abandoned for some more complex system, that the primitive man, whatever he may have been, has in the course of ages divaricated into three extreme types, represented by the Caucasian of Europe, the Mongolian of Asia, and the Ethiopian of Africa, and that all existing individuals of the species can be ranged around these types, or somewhere or other between them. Large numbers are doubtless the descendants of direct crosses in varying proportions between well-established extreme forms; for, notwithstanding opposite views formerly held by some authors on this subject, there is now abundant evidence of the wholesale production of new races in this way. Others may be the descendants of the primitive stock, before the strongly marked existing distinctions had taken place, and therefore present, though from a different cause from the last, equally generalised characters. In these cases it can only be by most carefully examining and balancing all characters however minute, and finding out in what direction the preponderance lies, that a place can be assigned to them. It cannot be too often insisted on, that the various groups of Mankind, owing to their probable unity of origin, the great variability of individuals, and the possibility of all degrees of intermixture of races at remote or recent periods of the history of the species, have so much in common that it is extremely difficult to find distinctive characters capable of strict definition, by which they may be differentiated. It is more by the preponderance of certain characters in a large number of members of a group, than by the exclusive or even constant possession of these characters in each of its members, that the group as a whole must be characterised.

Bearing these principles in mind, we may endeavour to formulate, as far as they have as yet been worked out, the distinctive features of the typical members of each of the three great divisions, and then show into what subordinate groups each of them seems to be divided.

To begin with the Ethiopian, Negroid or Melanian, or "black" type. It is characterised by a dark, often nearly black, complexion; black hair, of the kind called "frizzly" or, incorrectly, "woolly," *i.e.* each hair being closely rolled up upon itself, a condition always associated with a more or less flattened or elliptical transverse section; a moderate or scanty development of beard; an almost invariably dolichocephalic skull; small and moderately retreating malar bones (mesopic face[1]); a very broad and flat nose, platyrhine in the skeleton; moderate or low orbits, prominent eyes; thick, everted lips; prognathous jaws, large teeth (macrodont); a narrow pelvis (index in the male 90 to 100); a long fore arm (humero-radial index &c.) and certain other proportions of the body and limbs which are being gradually worked out and reduced to numerical expression as material for so doing accumulates.

The most characteristic examples of the second great type, the Mongolian or Xanthous or "yellow," have a yellow or brownish complexion; coarse, straight hair, without any tendency to curl, and nearly round in section, on all other parts of the surface except the scalp, scanty and late in appearing; a skull of variable form, mostly mesocephalic (though extremes both of dolichocephaly and brachycephaly are found in certain groups of this type); a broad and flat face, with prominent, anteriorly-projecting malar bones (platyopic face); nose small, mesorhine or leptorhine; orbits high and round, with very little development of glabella or supraciliary ridges; eyes sunken, and with the aperture between the lids narrow; in the most typical members of the group with a vertical fold of skin over the inner canthus, and with the outer angle slightly elevated; jaws mesognathous; teeth of moderate size (mesodont); the proportions of the limbs and form of the pelvis have yet to be worked out, the results at present obtained showing great diversity among different individuals of what appear to be well-marked races of the group, but this is perhaps due to the insufficient number of individuals as yet examined with accuracy.

The last type, which, for want of a better name, I will call by that which has the priority, Caucasian, or "white," has usually a light-complexioned skin (although in some, in so far aberrant cases, it is as dark as in the Negroes); hair fair or black, soft, straight, or wavy, in section intermediate between the flattened and cylindrical form; beard fully developed; form of cranium various, mostly mesocephalic; malar bones retreating; face narrow and projecting in the middle line (pro-opic); orbits moderate; nose narrow and prominent (leptorhine); jaws orthognathous; teeth small (microdont); pelvis broad (pelvic index of male 80); forearm short, relatively to humerus (humero-radial index 74).

In endeavouring further to divide up into minor groups the numerous and variously-modified individuals which cluster around one or other of these great types, a process quite necessary for many practical or descriptive purposes, the distinctions afforded by the study of physical characters are often so slight that it becomes necessary to take other considerations into account, among which geographical distribution and language hold an important place.

I. The Ethiopian or Negroid races may be primarily divided as follows:—

A. African or typical Negroes—inhabitants of all the

[1] From the President's Anniversary Address to the Anthropological Institute of Great Britain and Ireland, Jan. 27, 1885.

[1] Oldfield Thomas, in a paper read before the Anthropological Institute, Jan. 13, 1885.

lies in the fact that the glabella and supra-orbital ridges are generally well developed in the males, whereas in Africans this region is usually smooth and flat. The nose, also, especially in the northern part of their geographical range, New Guinea, and the neighbouring islands, is narrower (often mesorhine) and prominent. The cranium is generally higher and narrower. It is, however, possible to find African and Melanesian skulls quite alike in essential characters.

The now extinct inhabitants of Tasmania are probably pure, or aberrant, members of the Melanesian group, which have undergone a modification from the negro type, not by mixture with other races, but in consequence of long isolation, during which special characters have gradually developed. Being completely out of the track of all colonization and commerce, even of the most primitive kind, they were little liable to be subject to the influence of other races, and there is in fact nothing among their characters which could be accounted for in this way, as they are intensely exaggerated negro. No trend in the form of nose, prominence of maxilla, and size of teeth, explicable on the character of life, and plateau, chiefly in width of skull in the parietal region. A race with any of the Polynesian or Malay races sufficiently strong to produce this result, in all probability, must have left some traces on other parts of their organization.

In the other hand, in many parts of the Melanesian region there are distinct evidences of large admixture with Negrito, Malay, and Polynesian elements in varying proportions, producing numerous physical modifications. In the south-east part of the great island of New Guinea (with all of those lines around it) this mixture can be traced to the complete Micronesian in the north, and New Zealand in the south, though the Melanesian element is present, it is completely overlaid by the Polynesian, but in other localities (as, e.g., in some of the islands of the Pacific and Malay Archipelago) the Melanesian element is the predominant one. Every possible factor in the composition of the natives

The inhabitants of the continent of Australia have long been considered as members of the Negroid complexion, but recent researches have shown that the characteristic physical features of this race have been much exaggerated. They have, in fact, been stated in the most extravagant manner possible. The [illegible] supposed to be [illegible] and lengthy [illegible], [illegible] in the opposition that [illegible] all, that [illegible] [illegible] [illegible]

I know nothing to exclude the possibility of the Australians being mainly the direct descendants of a very primitive human type, from which the frizzly-haired Negroes may be an offset. This character of hair must be a specialisation, for it seems very unlikely that it was the attribute of the common ancestors of the human race.

D. The fourth branch of the Negroid race consists of the diminutive round-headed people called Negritos, still found in a pure or unmixed state in the Andaman Islands, and forming a substratum of the population, though now greatly mixed with invading races, especially Malays, in the Philippines, and many of the islands of the Indo-Malayan Archipelago, and perhaps of some parts of the southern portion of the mainland of Asia. They also probably contribute to the varied population of the great island of Papua or New Guinea, where they appear to merge into the taller, longer-headed and longer-nosed Melanesians proper. They show, in a very marked manner, some of the most striking anatomical peculiarities of the Negro race, the frizzly hair, the proportions of the limbs, especially the humero-radial index, and the form of the pelvis; but they differ in many cranial and facial characters, both from the African Negroes on the one hand, and the typical Oceanic Negros, or Melanesians, on the other, and form a very distinct and well-characterised group.

II.—The principal groups that can be arranged around the Mongolian type are—

A. The Eskimo, who appear to be a branch of the typical North Asiatic Mongols, who in their wanderings northwards and eastwards across the American continent, isolated almost as perfectly as an island population would be, hemmed in on one side by the eternal Polar ice and on the other by hostile tribes of American Indians, with which they rarely, if ever, mingled, have gradually developed characters most of which are strongly-expressed modifications of those seen in their allies who still remain on the western side of Behring's Straits. Every special characteristic which distinguishes a Japanese from the average of mankind is seen in the Eskimo in an exaggerated degree, so that there can be no doubt about their being derived from the same stock. It has also been shown that these special characteristics gradually increase from west to east, and are seen in their greatest perfection in the inhabitants of Greenland; at all events, in those where no crossing with the Danes has taken place. Such scanty remains as have yet been discovered of the early inhabitants of Europe present no structural affinities to the Eskimo, although it is not unlikely that similar external conditions may have led them to adopt similar modes of life. In fact, the Eskimo are such an intensely specialized race, perhaps the most specialized of any in existence, that it is probable that they are of comparatively late origin, and were not as a race contemporaries with the men whose rude flint tools found in our drifts excite so much interest and speculation as to the makers, who have been sometimes, though with little evidence to justify such an assumption, reputed to be the ancestors of the present inhabitants of the northernmost parts of America.

B. The typical Mongolian races constitute the present population of Northern and Central Asia. They are not very distinctly, but still conveniently for descriptive purposes, divided into two groups, the Northern and the Southern.

a. The former, or Mongolo-Altaic group, are united by the affinities of their language. These people, from the cradle of their race in the great central plateau of Asia, have at various times poured out their hordes upon the lands lying to the west, and have penetrated almost to the heart of Europe. The Finns, the Magyars, and the Turks, are each the descendants of one of these waves of incursion, but they have for so many generations intermingled with the peoples through whom they have passed in their migrations, or have found in the countries to which they have ultimately settled, that their original physical characters have been completely modified. Even the Lapps, that diminutive tribe of nomads inhabiting the most northern parts of Europe, supposed to be of Mongolian descent, show so little of the special attributes of that branch, that it is difficult to assign them a place in it in a classification based upon physical characters. The Japanese are said by their language to be allied rather to the Northern than to the following branch of the Mongolian stock.

b. The Southern Mongolian group, divided from the former chiefly by language and habits of life, includes the greater part of the population of China, Thibet, Burmah and Siam.

C. The next great division of Mongoloid people is the Malay, subtypical, it is true, but to which an easy transition can be traced from the most characteristic members of the type.

D. The brown Polynesians, Malayo-Polynesians, Maohoris, Sawaioris, or Kanakas, as they have been variously called, seen in their greatest purity in the Samoan, Tongan, and Eastern Polynesian Islands, are still more modified, and possess less of the characteristic Mongolian features; but still it is difficult to place them anywhere else in the system. The large infusion of the Melanesian element throughout the Pacific, must never be forgotten in accounting for the characters of the people now inhabiting the islands, an element in many respects so diametrically opposite to the Mongolian, that it would materially alter the character, especially of the hair and beard, which has been by many authors a stumbling-block to the affiliation of the Polynesian with the Mongol stock. The mixture is physically a fine one, and in some proportions produces a combination, as seen, for instance, in the Maories of New Zealand, which in all definable characters approaches quite as near, or nearer, to the Caucasian type, than either of the stocks from which it may be presumed derived. This resemblance has led some writers to infer a real extension of the Caucasian element at some very early period with the Pacific Islands, and to look upon their inhabitants as the product of a mixture of all three great types of men. Though this is a plausible theory, it rests on little actual proof, as the combination of Mongolo-Malayan and Melanesian characters in different degrees to the local variations certain to arise in communities so isolated from each other and exposed to such varied conditions as the inhabitants of the Pacific Islands, would probably account for all the modifications observed among them.

E. The native population (before the changes wrought by the European conquest) of the great continent of America, excluding the Eskimo, present, considering the vast extent of the country they inhabit and the great differences of climate and other surrounding conditions, a remarkable similarity of essential characters, with much diversity of detail.

The construction of the numerous American languages of which as many as twelve hundred have been distinguished, is said to point to unity of origin, as, though widely different in many respects, they are all, or nearly all, constructed on the same general grammatical principle—that called *polysynthesis*—which differs from that of the languages of any of the Old World nations. The mental characteristics of all the American tribes have much that is in common; and the very different stages of culture to which they had attained at the time of the conquest, as that of the Incas and Aztecs, and the hunting or fishing tribes of the north and south, which have been quoted as evidence of diversities of race, are greater than those between different nations of [illegible] as Gauls and Germans on the one hand, and

Romans on the other, in the time of Julius Cæsar. Yet all these were Aryans, and in treating the Americans as one race it is not intended that they are more closely allied than the different Aryan people of Europe and Asia. The best argument that can be used for the unity of the American race—using the word in a broad sense—is the great difficulty of forming any natural divisions founded upon physical characters. The important character of the hair does not differ throughout the whole continent. It is always straight and lank, long and abundant on the scalp, but sparse elsewhere. The colour of the skin is practically uniform, notwithstanding the enormous differences of climate under which many members of the group exist. In the features and cranium certain special modifications prevail in different districts, but the same forms appear at widely-separated parts of the continent. I have examined skulls from Vancouver's Island, from Peru, and from Patagonia, which were almost undistinguishable from one another.

Naturalists who have admitted but four primary types of the human species, have always found a difficulty with the Americans, hesitating between placing them with the Mongolian or so-called "yellow" races, or elevating them to the rank of a primary group. Cuvier does not seem to have been able to settle this point to his own satisfaction, and leaves it an open question. Although the large majority of Americans have in the special form of the nasal bones, leading to the characteristic high bridge of the nose of the living face, in the well-developed superciliary ridge and retreating forehead, characters which distinguish them from the typical Asiatic Mongol, in so many other respects they resemble them so much that, although admitting the difficulties of the case, I am inclined to include them as aberrant members of the Mongolian type. It is, however, quite open to any one adopting the Negro, Mongolian, and Caucasian as primary divisions, also placing the Americans apart as a fourth.

Now that the high antiquity of man in America, perhaps as high as that he has in Europe, has been discovered, the puzzling problem, from which part of the Old World the people of America have sprung, has lost its significance. It is quite as likely that the people of Asia may have been derived from America as the reverse. However this may be, the population of America had been, before the time of Columbus, practically isolated from the rest of the world, except at the extreme north. Such visits as those of the early Norsemen to the coasts of Greenland, Labrador, and Nova Scotia, or the possible accidental stranding of a canoe containing survivors of a voyage across the Pacific or the Atlantic, can have had no appreciable effect upon the characteristics of the people. It is difficult, therefore, to look upon the anomalous and special characters of the American people as the effects of crossing, as was suggested in the case of the Australians, a consideration which gives more weight to the view of treating them as a distinct primary division.

III. The Caucasian, or white division, according to my view, includes the two groups called by Prof. Huxley Xanthochroi and Melanochroi, which, though differing in colour of eyes and hair, agree so closely in all other anatomical characters, as far, at all events, as has at present been demonstrated, that it seems preferable to consider them as modifications of one great type than as primary divisions of the species.

Whatever their origin, they are now intimately blended, though in different proportions, throughout the whole of the region of the earth they inhabit; and it is to the rapid extension of both branches of this race that the great changes now taking place in the ethnology of the world is mainly due.

A. The Xanthochroi, or blonde type, with fair hair, eyes, and complexion, chiefly inhabit Northern Europe—Scandinavia, Scotland, and North Germany—but, much mixed with the next group, they extend as far as Northern Africa and Affghanistan. Their mixture with Mongoloid people in North Europe has given rise to the Lapps and Finns.

B. Melanochroi, with black hair and eyes, and skin of almost all shades from white to black. They comprise the great majority of the inhabitants of Southern Europe Northern Africa, and South-west Asia, and consist mainly of the Aryan, Semitic, and Hamitic families. The Dravidians of India, and probably the Ainos of Japan, the Maoutze of China, also belong to this race, which may have contributed something to the mixed character of some tribes of Indo-China and the Polynesian Islands, and, as before said, given at least the characters of the hair to the otherwise Negroid inhabitants of Australia. In Southern India, they are probably mixed with a negrito element, and in Africa, where their habitat becomes conterminous with that of the Negroes, numerous cross races have sprung up between them all along the frontier line. The ancient Egyptians were nearly pure Melanochroi, though often showing in their features traces of their frequent intermarriage with their Ethiopian neighbours to the south. The Copts and fellahs of modern Egypt are their little-changed descendants.

In offering this scheme of classification of the human species, I have not thought it necessary to compare it in detail with the numerous systems suggested by previous anthropologists. These will all be found in the general treatises on the subject. As I have remarked before, in its broad outlines it scarcely differs from that proposed by Cuvier nearly sixty years ago, and that the result of the enormous increase of our knowledge during that time having caused such little change, is the best testimony to its being a truthful representation of the facts. Still, however, it can only be looked upon as an approximation. Whatever care be bestowed upon the arrangement of already acquired details, whatever judgment be shown in their due subordination one to another, the acquisition of new knowledge may at any time call for a complete or partial re-arrangement of our system.

W. H. FLOWER

NOTES

WE have to announce the death of Mr. Geoffrey Nevill, who died at Davos Platz on the 10th inst. He was for many years Assistant Superintendent in the Calcutta Museum, and had charge there of two conchological collections, which were entirely arranged and named by him. He did some good work there.

IN a recent issue we gave some account of the Liverpool Corporation free lectures, which were then in the experimental stage. Since then the lectures have been continued every winter, and we should like to call the attention to them of those of our readers who are interested in the promotion of elementary scientific knowledge among the lower classes, and especially those who have, either as town-councillors or magistrates in their respective towns, influence in their own localities. We have before us a programme of the present course, copies of which can be obtained from Mr. P. Cowell, Liverpool Free Public Library. The lectures are given every Monday, Tuesday, Wednesday, and Thursday from January 5 to March 12 inclusive, in the Rotunda Lecture Hall of the Library, which holds more than 1500 people. The entire expense of them is defrayed by the Corporation, and admission is perfectly free. A member of the Corporation invariably occupies the chair at each lecture. Mr. Lant Carpenter lectured there on the night of February 12 upon "Sunspots and their Connection with Weather Changes," to an audience of great extent. It was composed almost exclusively of "the great unwashed," who had come in straight from their work, or, alas, in some cases, from their inforced idleness; the Liverpool dock porters were there in

their hundreds! The audience, though larger than usual, was not exceptionally so. Notwithstanding the somewhat technical and abstruse nature of the subject, involving an explanation of the application of the principles of spectrum analysis to solar physics (in which the oxyhydrogen lantern illustrations were, during half the lecture, a great assistance), this large audience of *unskilled labourers*, men and youths, listened for nearly an hour and a half with the closest attention, strongly resenting the solitary attempt at interruption, and at the close of the lecture were most enthusiastic in their approval. Why cannot the same thing be done in other large towns, and must we wait for London municipal reform to get it done in the metropolis?

IN *La Nature* of February 14, under the title of "The Struggle for Existence," is a curious account of an attack on a dog by a flock of crows. The account of the affray is given by M. Magin, director of St. Albert Glassworks, Anecht, Nord. M. Magin states that in January last, when the ground was covered with snow, his dog (a *Griffon*) was in a field adjoining the workshop, when he was attacked by a flock of crows. About a hundred were in the field, but only about thirty actually joined. Dividing themselves into two parties, one attacked the poor dog before, and another behind. Rising about two metres above ground, they would plunge their beaks invariably into a bleeding wound. When the dog was rescued by the workmen he was in a dilapidated state, his eye torn out, and a deep wound in the neck. The crows remained about the place for some time after the rescue of the dog.

THE Statistical Society proposes to celebrate the jubilee of its foundation on June 22 and 23 next. It is proposed to invite to the celebration distinguished statisticians from foreign countries, several of whom, it is hoped, will be Government representatives.

THE Mersey tunnel was opened on the 13th inst.; it was begun in the end of 1879. It may be stated that the length of the projected railway is two miles and a half, from James Street, Liverpool, to Green Lane, Tranmere; and from shaft to shaft the distance immediately beneath the River Mersey is about one mile. For the two stations in James Street, Liverpool, and Hamilton Square, Birkenhead, the necessary excavations were some time ago completed.

FOR the first time, we believe, in English warfare, balloons are to be utilised in the Soudan Campaign. The transport *Queen* sailed on Monday from the Thames with the Balloon and Telegraph Corps for the Suakin Expeditionary Force. Three balloons are taken out with all the necessary appliances to be used for taking observations of the enemy's positions. All have been made at the School of Engineering. Compressed hydrogen for inflating the balloons is carried in iron cylinders, 12 feet long by 1 foot diameter, but these are only for a reserve supply, and, weighing half a ton each, will be left behind at the base of operations, where, also, a gas factory and pumping station will be put up. Materials for this purpose are on board the ship, including a small gas-holder, and all the necessary chemicals for making more gas are provided. About a hundred lighter cylinders, easily carried by men, form part of the equipment. Each of these, which are 9 feet long, contains 120 feet of hydrogen in a compressed state, and, as they are emptied, they will be taken back to be recharged at the Suakin station. One waggon, containing one ton of stores, will suffice for a balloon ascent. Captive ascents only will be made, in which the balloons will be tethered by rope or wire, both of which are taken. Communication by telephone will be established between the car and the ground, and the chief employment of the balloons will be to take observations of the enemy's movements.

A MEETING, called together with the object of obtaining a more extended support for the Parkes Museum, was [illegible]t the Mansion House on Friday, the Lord Mayor (Mr. Alderman Nottage) presiding. The Lord Mayor, in opening the proceedings, said the object of the organisers of the Parkes Museum was to promote the physical welfare and h[illegible]ness of, he might say, the human race. Capt. Douglas G[illegible] read a statement on behalf of the joint committee of members of council, from which it appeared that the museum was founded at a meeting presided over by Sir William Jenner in July, 18[illegible], in memory of the late Edmund Alexander Parkes, who was the first Professor of Hygiene in this country. The Queen and members of the Royal Family had subscribed to the fund, and had taken great interest in the Institution. Out of it had grown the International Medical and Sanitary Exhibition, and the Health Exhibition. The Museum is open free for a part of each day in the week. The lectures have been given for the benefit of the Working Men's Club and Institute Union, the Institute of Builders' Foremen and Clerks of Works, and the Metropolitan Building Societies. The Museum has also been placed at the disposal of teachers of hygiene, and classes have since come from University College, St. Bartholomew's Hospital, Guy's Hospital, the Royal Engineers, and the Young Men's Christian Association. The reading-room, with its valuable library of sanitary literature, has always been a distinguished feature of the Museum, and has recently been enhanced by the addition of 1500 volumes contributed by the Council of the International Health Exhibition. For upwards of eighty years the Museum has been maintained by voluntary contributions. To keep it open to the public it has become necessary that at least £[illegible] should be raised by the end of the present month. The Master of Cambridge moved "That the statement which has been read affords conclusive evidence that the Parkes Museum of Hygiene is meeting a great educational want, and is worthy of increased support." There were two chief considerations which presented themselves to his mind—the first was, that the Society was clear out of the difficulties it was in; and next, the Museum was now established on a sure footing, so as to enable its advantages to be extended. The premises at present occupied by the Society must be re-engaged, and it would be necessary to widen its scope in coming years. Mr. Ernest Hart said he thought the wealthy and practical City of London could not be proud of its action towards this valuable Institution. Nearly all the support of the Museum came from the West-end, and were largely given among the professional and medical classes. The importance of the Museum might be gathered from an outside indication—namely, that the idea had been imitated, and the example extended in the United States, in France, in Italy, and Japan. He thought they were entitled to support, not only from the great merchants and bankers of the City, but from the Corporation and the City Companies. The Parkes Museum was a mere skeleton sanitary museum. It was without a laboratory, without lectures, without demonstrators. In other countries the State subsidised their Health Museums, and that it was deserving the highest recognition from a merely commercial point of view had been conclusively shown by Sir James Paget's statistics as to the pecuniary national loss from preventible disease. A list of subscriptions amounting to 1006*l.* was announced.

THE death is announced of Mr. Hodder M. Westropp, well-known archæologist, at the age of sixty-four years.

PROF. JOHN MARSHALL on Saturday, in the theatre of the Royal College of Surgeons, delivered the annual Hunterian oration before a distinguished medical audience. The [illegible] considered the mental attitude which "the [illegible] of Surgery" would probably assume t[illegible] salient opinions of our times. Th[illegible] research and the growth of a new [illegible] logy, [illegible]

SHOCKS of earthquake continue to be felt in the south of Spain. A telegram from Granada on the 12th stated that slight shocks continued to be felt at Alhama, and on that day there was a shock at Terre del Campo near Jaen. There were also shocks in the evening of the 14th at Granada and Velez Malaga.

Our Nature takes advantage of the attention at present directed to South Africa, to recall the story of the first astronomical expedition to the Cape. The first expedition ever sent across the seas for such a purpose as astronomical observation was that of Jean Richer, which went to Cayenne on behalf of the Paris Academy, in order that simultaneous observations of Mars should be made there and in Paris. The Cape expedition took place thirty years later. Baron Krosigk, its promoter, had founded a private observatory at Berlin, where observations of the moon's culminations were made for a long period, and observers were sent to the Cape to make corresponding observations there. It was hoped that by collating the observations in both places the moon's parallax would be obtained. So far as this was concerned, the expedition failed. Wagner, the founder and first head of the public observatory at Berlin, carried out his part of the work in Prussia, but Kolb, who had charge of the Cape expedition, was guilty of great negligence, so that the results were inconsistent and unsatisfactory. In 1719 he published a book entitled "Capui bonæ spei hodiernum," in which he described everything at the Cape except what he was sent to do. The work which Krosigk hoped to do then was not completed for another forty years, when Lacaille and Lalande made the necessary observations, the one at the Cape, the other in Paris.

MR. CARL ARMBRUSTER will begin a course of five lectures at the Royal Institution on "The Life, Theory, and Works of Richard Wagner," on Saturday, February 28 (with vocal and instrumental illustrations).

IN order to ascertain the truth of the assertions recently made by certain ichthyologists in regard to the capacity of Canadian salmon to exist in sea water, an experiment has been made in the South Kensington Aquarium, several specimens being deposited in one of the salt-water tanks, where they lived for eight days, when they expired in rapid succession. This entirely dissipates the theory which obtained credence hitherto in numerous quarters.

THE additions to the Zoological Society's Gardens during the past week include two Laughing Kingfishers (*Dacelo gigantea*) from Australia, two Hooded Crows (*Corvus cornix*) from Connemara, Ireland, presented by Lady Brassey, F.Z.S.; a Sharp-nosed Crocodile (*Crocodilus acutus*) from Nicaragua, presented by Mr. C. G. Brown, M.R.C.S.; a Common Boa (*Boa constrictor*) from South America, deposited; a Cook's Phalanger (*Phalangista cookii* ♀) from Australia, a Globose Curassow (*Crax globicera*) from Central America, two Stanley Parrakeets (*Platycercus icterotis jv.*) from Western Australia, purchased; two Long-fronted Gerbilles (*Gerbillus longifrons*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

AN ANCIENT OCCULTATION OF JUPITER.—In Roger de Hoveden's Chronicle, under the year 756, we read:—"Eodem anno Balthere anachoritæ vitam sanctorum scriptus est, et migravit ad Dominum; Luna autem sanguineo rubore superducta octavo Kalendas Decembris quindecima ætate, id est plena, sicque paulatim decrescentibus tenebris ad lucem pristinam pervenit; nam, mirabiliter, ipsam lunam sequente lucida stella et pertranseunte tanto spatio eam antecedebat illuminatam, quanto sequebatur, antequam esset obscurata." (*Chronica Magistri Rogeri de Hovedene*, edited by William Stubbs, M.A., vol. i. p. 7.) Simeon of Durham records the phenomenon in similar terms, and also dates it in A.D. 756; but this has been long known to be a mistake, the eclipse of the moon, to which reference is made, having taken place on the evening of November 8, A.D. 755.

Calvisius at first supposed that the star which was occulted by the moon at the time of this eclipse might have been the "Oculus Tauri" or Aldebaran, and submitted the point to computation, though, as Pingré remarks, this was unnecessary as a star with a latitude of more than 5° could not be occulted by an eclipsed moon. Struyck, in the first edition of his well-known geographical and astronomical treatise, published in 1750, stated that, on calculating the place of the moon, he had found there was no bright star near her at the time, and it occurred to him that perhaps the planet Jupiter might have been occulted by the eclipsed moon, which, on applying "Whiston's Tables," he ascertained to have been actually the case; the tables referred to were those of Halley in their early form. Struyck found the time of the planet's disappearance 6h. 30m. at London, and that of the reappearance 6h. 57m. (see Zach's *Monatliche Correspondenz*, i. 576).

The following results will probably supply a much closer approximation to the actual circumstances of the phenomenon recorded by the English historians.

For the elements of the eclipse of the moon we have—

G.M.T. of opposition in R.A., 755, November 23, 6h. 25m. 7s.

						°	′	″
R.A.	...	...	...	...	...	63	3	15
Moon's hourly motion in R.A....					...		30	54
Sun's	,,	,,	...	...	...		2	41
Moon's declination	...	...	...			21	4	20 S.
Sun's	,,	...	...		...	21	16	57 S.
Moon's hourly motion in declination					...		8	8 N.
Sun's	,,	,,	,,				0	28 S.
Moon's horizontal parallax			...		...		54	16
Sun's	,,	,,	...		...		0	9
Moon's true semi-diameter			...		...		14	47
Sun's	,,	,,	...		...		0	16

The sidereal time at Greenwich noon was 16h. 7m. 34s. The moon was full at 6h. 30m.

From the above elements we find—

								h.	m.
First contact with the shadow	...	...				Nov.	23,	4	38
Beginning of total phase	...	...	...				,,	5	47
End of total phase	...	...	...				,,	7	13
Last contact with the shadow	...	...					,,	8	27

Employing Bouvard's Tables of Jupiter the following are the positions of the planet:—

Paris M.T.			Apparent R.A.				Apparent decl.		
h.			°	′	″		°	′	″
7	...	...	64	23	25	...	20	50	12 N.
8	...	...	64	23	3	...	20	50	9 N.

The log. distance of Jupiter from the earth was 0·6163.

Calculating the circumstances of the occultation for London, we find with the above data that the disappearance would take place at 7h. 35m., and the reappearance at 8h. 33m.; the former would therefore occur while the moon was still partially eclipsed, and the latter a few minutes after she emerged from the earth's shadow.

It may be mentioned that the moon's place has been determined in the same manner as for the occultation of Mars observed by the Chinese at Siganfou B.C. 69, February 14, and that of Venus, A.D. 361, March 20, at Nanlin, the phenomena being well represented in both cases, as previously detailed in this column. No doubt the introduction of Leverrier's Table of Jupiter would somewhat modify the times of disappearance and reappearance on November 23, 755, here given; our object has been merely to confirm Struyck's explanation of the recorded phenomenon.

ASTRONOMICAL PHENOMENA FOR THE WEEK, 1885, FEBRUARY 22-28

(For the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on February 22

Sun rises, 7h. 1m.; souths, 12h. 13m. 39·6s.; sets, 17h. 26m.; decl. on meridian, 10° 1′ S.; Sidereal Time at Sunset, 3h. 37m.

It is announced that Mr. Sidney Webb will succeed Mr. Thomas Gibson Bowles as Chairman of the Board of Inland Revenue.

A series of lectures on "Explorers of the Portuguese" will be commenced in the theatre of the new Museum at Lisbon, by Senhor Ferreira Deusdado, and will chronicle the advance of geographical knowledge, especially that of geography and travel.

At the meeting of the Académie des Sciences at Paris on the 9th inst., letters were read from the Travelling Commission sent to Zanzibar to observe the total eclipse of the sun on January 1, 1889. The Commissioners, MM. Trépied, Lagrula, Bertrand, Director of the Observatory of Algiers, and Lieutenant Caron, of the Navy, have arrived at Zanzibar, and are making preparations for the observation of the eclipse. The weather is favourable, and the instruments are in order. The Commissioners will be joined by Mr. Dunn, Director of the Royal Observatory at the Cape of Good Hope, who is coming to Zanzibar for the purpose of observing the eclipse. Mr. Dunn has been appointed a Commissioner in place of Mr. Tennant, who is unable to go to Zanzibar. He will proceed from the Cape to Zanzibar in the Dromedary, which will be placed at the disposal of the Commissioners.

CANAL MODIFICATIONS OF ACHROMATIC LENSES AND ABBE'S NEW EYEPIECE PRISMS

[illegible]

Foucault's prism, about the same as in Ahrens's prism, and much less than in Nicol's prism.

(2) Only half the prism is made of Iceland spar, a material which is becoming deplorably scarce and expensive (I question if there is in England or elsewhere a piece of spar fit to make a Nicol's prism of 5 cm. aperture). The saving, however, is not so great as it appears, since the spar-prisms *a* and *b* are constructed on Wollaston's principle, and involve a certain waste of material.

(3) The combination is not quite free from distortion and chromatic aberration (the latter being due, of course, to irrationality of dispersion; it is practically impossible to achromatise spar with glass), but the imperfection is not serious enough to interfere with its use for many optical purposes, especially as a polariser.

(4) In using it, a diaphragm should be placed in such a position as to limit the entering cone of rays to 25°, since at a greater angle (at any rate, on one side of the field) the ordinary rays are not separated by total reflexion.

Doubtless the prism may be improved upon by better authorities than myself; but I think that the principle of using a "double-image" prism to increase the divergence of the ordinary and extraordinary rays before one of them is separated by total reflexion is worth attention.

Ahrens's polarising prism is certainly a remarkable one. I do not think that a double-image prism has ever been previously constructed in which the extraordinary ray emerges without deviation, while the other ray is deviated to the extent of very nearly 60°.

H. G. MADAN

Eton College, February 17

THE RESULTS OF THE SCIENTIFIC EXPEDITION TO SODANKYLÄ

THE Government of Finland having provided further funds, the Expedition has continued its researches at Sodankylä, in Finnish Lapland, during the year 1883-84 (NATURE, vol. xxvii. pp. 322 and 389). The plan of working this year was chiefly confined to the study of the terrestrial galvanic currents, atmospheric electric currents, and the phenomena of light produced by the apparatus constructed by me for the purpose. The number of daily meteorological and magnetic observations was restricted to three, viz. at 6 a.m., 2 and 10 o'clock p.m., Göttingen mean time, but on the 1st and 15th of each month observations were taken every five minutes, as in the previous year, and on the 8th and 22nd of each month, from 8.30 p.m. till 10.30 p.m., observations were taken every half minute.

The general meteorological and magnetic observations were continued without interruption until August 22, 1884. In the account of the observations on the luminous phenomena will be included a *résumé* of the general character of the weather of this year.

The Terrestrial Current.—From the middle of September 1882 the Expedition has observed the terrestrial currents, as well as the magnetic variations. For this purpose two circuits about 5 km. long were placed north-south and east-west. They were connected to platina plates 1 decimetre square, and buried about 1·3 m. below the surface of the ground. The southern and eastern plates were about 0·5 km. from the station. During this year the observations were confined chiefly to the variations of the terrestrial current, hence no attempt was made to separate the electromotive force of the terrestrial current from that which was developed by the contact of the plates with the earth.

In the autumn of 1883 it became necessary to place fresh wires in the circuits, and at the same time the position of the plates was changed, so that each one was now about 2·5 km. from the station. The old circuit lying east and west was, however, left undisturbed for some time for the purpose of making comparisons.

It was not until the middle of January that observations of the terrestrial currents were commenced at the auxiliary station at Kultala, 68° 29′·5 N. (see Fig. 1). Here the circuits for the terrestrial current were placed so that the one lying north-south, 2·9814 km. long, was 3° west, and the east-west circuit, 4·5663 km. long, lay 69° north-west. This arrangement was made to permit the plates of the east and west being placed in the River Ivalo, and those lying north-south, in two affluents of this river. At this station attempts were made to eliminate that portion of the electromotive force which arose from the contact of the plates with "earth" (here the water) as well as the polari
The method employed was as follows:—With a Ma
electrometer, the sensitiveness of which had been exactly
sured by a "Daniell" normal element (about 18 divisions of
scale per volt), the electromotive force of all the four plate
the earth was determined. These were then joined in
different ways with a galvanometer, and the deviations noted.
Daniell normal element, furnished with an adjustable resist
slide, was then placed in the circuit in a contrary direction to
current, and the electromotive force was then reduced till
deviation was = 0. Thus the electromotive force of the diff
plates was obtained free of polarisation by means of an
trometer.

To eliminate the electromotive force arising from the con

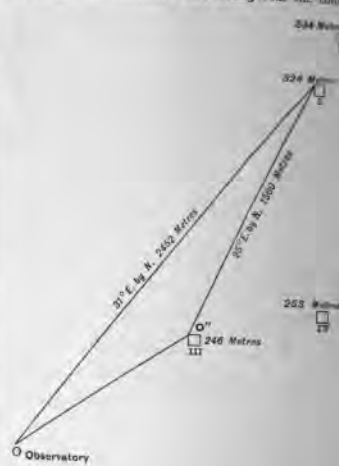

FIG. 1.—Plan of the position of the apparatus on the Pietarovaara Mountains.

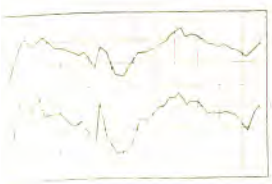
of the plates with the water, the latter were taken to
station and sunk in the river close by. They were connec
with a wire from the circuits resting on Mascart insulato
Their electromotive force was examined by means of an elec
meter, which was discharged each time by a plate of
amalgam sunk in the river. This experiment was also made
another manner. All the plates were sunk in a bucket of w
resting on Mascart insulators and connected with the earth
copper wire. The two latter experiments gave very
results. When the platina plates had been examined in
manner, they were placed in their former positions, after w
they were again examined both by the galvanometer and elec
meter. The details of this experiment, as well as those
others, must, however, be reserved for a special memoir.
the above-mentioned means results are shown free from
accidental disturbing influences. Some observations, throug



the atmosphere, i.e. from the zinc plate to the "discharging-apparatus."

For the future I will call this direction of the current *negative*, and the contrary direction from the atmosphere towards the earth *the positive*. The deviations of the galvanometer were very variable, and the variations characterised by sudden movements, first in one direction, then in another. With this apparatus observations were made at Sodankylä during last autumn and winter. The deviation of the current was first exactly noted, after which a Leclanché element was introduced into the conductor, first with the positive pole towards the earth, and then towards the mountain. By this process a value was obtained at each observation of the electromotive force in the circuit of the current. This consisted of two kinds, viz. one arising from the contact of the zinc plate with "earth" (here water), the other from the effect of the electricity in the air upon the apparatus. The first kind varies very little. Regarding the observations at Sodankylä it has been remarked that they showed, as I have said, a negative current, which however became sometimes positive in October and November, and particularly when the aurora borealis was visible.

The daily observations of the atmospheric current were made at Kultala in the same manner as at Sodankylä. During the months of January and February three more "discharging apparatus" were constructed close to this station, and another conducting wire was placed on Mascart insulators. Fig. 2 shows the position of the apparatus, whose elevation was as follows:—

Height above the River Ivalo		Height above sea-level
I. 324 metres	...	484 metres = 1630 feet
II. 334 ,,	...	494 ,, = 1664 ,,
III. 246 ,,	...	416 ,, = 1368 ,,
IV. 253 ,,	...	413 ,, = 1391 ,,

The distance between the station and the Apparatus I. was 3·626 km., and the distance between I. and II. 0·339 km. The following points are also shown by this sketch, viz.:—

O is a small observatory with a chimney; O" is the point where the conducting wires of the four apparatus were joined to two wires leading to the station.

With this apparatus numerous experiments were made, chiefly in the month of March, of the results of which the following is a brief *résumé*:—

(1) If two "discharging-apparatus" are placed at a given elevation and connected with a galvanometer there is no current, *i.e.* the deviation of the galvanometer equals 0.

(2) The Apparatus II., connected by a galvanometer to Apparatus I., always gave a positive current, the strength of which varied considerably. The following values selected as examples show the electromotive force, expressed in volts, during four days in March:—

March 18	March 19	March 20	March 21
0·1171	0·1161	0·1891	0·0530
0·1714	0·1400	0·3262	0·0530
		0·2632	
		0·2632	

These values were obtained by introducing a Leclanché element into the conductor in opposite directions. The electromotive force of this element was determined by comparison with a Daniell normal element. As there was a difference of 10 m. in the height of Apparatus II. and I., it may be noted that the electromotive force varied during the above four days between 0·0326 and 0·0053 volts per metre. The above two results show, *that the electromotive force of the electric currents of the atmosphere may be studied with regard to their strength, and its variations by means of two "discharging-apparatus" erected at different elevations.*

When two apparatus at equal elevations give zero, it clearly shows that the electromotive force observed only depends upon the difference in elevation, *i.e.* that electricity is distributed throughout the atmosphere, so that an electromotive force is produced, causing a current from the atmosphere towards the earth. The continued study with these four apparatus gave this singular result:—

(3) Close to the earth there is a stratum of positively electrified air, the potential of which is greater than that of the immediately overlying stratum, so that the potential diminishes from the surface of the earth to a minimum, to again increase at higher altitudes. The Apparatus III. and IV. situated in this stratum gave, combined with I. and II., a negative current from the earth to the atmosphere.

This result, so soon arrived at, rendered rather difficult the projected work with the four apparatus, and the [illegible] increased still more owing to the fact that the conductivity of the air diminishes rapidly nearer the earth. In order to [illegible] more minutely this peculiarity, two portable "discharging apparatus" were constructed, consisting of a cross of thin [illegible] which were placed several spirals of wires provided with the total number of points being thirty. These miniature apparatus, which I will call S_1 and S_2, were erected near [illegible] the most elevated point of Pietarintunturi, S_1 being 2 m. above the earth, and S_2 at the top of a pole 9·1 m. high. [illegible] supported on Mascart insulators, and separately connected to the stations by conducting wires. With this apparatus [illegible] was obtained from S_1 and S_2, *i.e.* negative, from the earth to the atmosphere. Great care was taken against any accidental defect in the conductor, or in the arrangement of the apparatus. The deviation obtained was very small, but quite [illegible]. The actual experiments with these apparatus were made on March 26 at 11 p.m., and lasted about three hours. As the experiments are of great importance I will describe [illegible] followed.

The night was chosen as the most favourable [illegible] on the mountain being then very slight. The observers [illegible] Granit and Roos, having telephoned that the experiments commence, the current was measured by the galvanometer, S_1 being then 2 m. and S_2 at 9·1 m. above the earth; [illegible] *was negative.* S_2 was then lowered to the same height as S_1, when *the deviation was* 0. S_2 was elevated to its former position, and now the deviation was negative as originally. S_2 was now attached to two poles—3 m. high—furnished with [illegible] insulators, and then raised by two men to a height of 4 m. *The deviation now became positive.*

This proved that the electric density of the stratum [illegible] diminishes up to the point at which the current changes, and that the minimum density lay between a height of 2 and 4 m.

It would have been very interesting to have continued these experiments and further extended them, but this could not be done, as the stay on the mountain became impossible.

I went up on March 25 to examine the apparatus and convince myself that no mistakes had been made, and as the temperature was not more than −12° C. it was impossible except with the back to the wind, for if the face was turned towards it, in a few moments the flesh became benumbed, breathing difficult and painful. On the mountain there is nearly always wind, but its strength was less at night.

These experiments with the portable apparatus are to be resumed next spring at Sodankylä under the superintendence of Mr. Biese, but as it is very probable that the electric state of the atmosphere will then be totally different, it is impossible to foretell whether they will give the anticipated results.

(4) From the stratum which lies some feet above the earth the electromotive force increases with the differences in height of the "discharging-apparatus." It has not been possible to [illegible] exactly the laws which regulate this increase, but it seems that the electromotive force increases more rapidly than in proportion to the difference in height.

The above results were obtained on clear days. The condition of the atmosphere affects the resistance of the conductor, and appears also to act upon the electromotive force.

On one of the small apparatus, S_1, a number of points were furnished with wicks soaked in petroleum; when these were lighted the effect was measured, and it appeared that the current was diminished a little, but the electromotive force remained unchanged. Further results obtained from the observations depend on a detailed examination of the materials collected.

Study of the Luminous Phenomena caused by the "Discharging Apparatus."—Before passing to a final *résumé* of the results of these researches, I will refer in general terms to the meteorological character of the year, which are very important in relation to this subject. It is very seldom that the winter in Lapland is as mild as the last one was. There was not much rain or snow, but it snowed nearly every day, so that the days when there was a clear sky can easily be counted. It is only in perfectly calm weather that the luminous electric phenomena are visible, and this only happens when the moonlight is not too bright. Consequently there were very few evenings when the luminous phenomena could be successfully observed.

ce (nimbus), and the brightness
1 2 when this had lasted about
half an hour, a luminous phenomenon in the shape of white clouds rose in flames from Apparatus I. *This gave the reaction in the spectroscope, and was very distinct, even to the naked eye.* At a signal, the machine was again put in motion, and now the flames followed each other every time, giving the reaction in the spectroscope. This reaction had sometimes a certain peculiarity: although the slit of the spectroscope was very straight, the line of the aurora was rather broad, and was followed by a continuous and very distinct spectrum towards F. At eight o'clock the machine was stopped, and the flames became fewer and feebler. At 8.15 p.m. the machine was again put in motion, with the same result as before. Presently a fog covered the summit of the mountain, and the experiments ceased at 8.40 p.m.

February 7.—The clouds were about 5 C.S. (5/10 cirro-stratus), hence the reactions could only be obtained as projections upon the bright spectrum of the moon. Now and then a very feeble reaction was obtained towards the north and west, but the Apparatus I. gave none of them. However, when the Holtz machine was put in motion, a very distinct one was obtained, particularly when sparks were emitted. After a Geissler tube had been placed in the conductor of the machine the reaction became still more intense, and was very distinct when the discharge was accompanied by *sparks*. Never had I obtained so intense a reaction. Mr. Biese again remarked that no absorption-band had been observed near *D* in the spectrum of the moon, although its intensity varied considerably. From these data may be inferred:—

(1) That the "discharging-apparatus" produces on certain occasions a diffuse light which gives the spectral reaction of the aurora borealis.

(2) That a Holtz machine placed in motion in the conductor intensifies the phenomenon, if it already exists, and may even produce it under favourable external conditions.

(3) This luminous phenomenon is invisible to the naked eye if the moonlight is very bright, but even then the spectroscope often shows its presence.

After my experience of the power of the "discharging-apparatus" to produce luminous phenomena in the *form of rays*, I thought the phenomenon would appear easily. The following conditions are however, I have discovered, necessary for this: *a clear sky, low temperature*, and a *relatively low barometer*. These conditions have been very rare this winter, and when they have been present it was in an imperfect manner. However, the phenomenon was seen twice, viz. on February 27 and March 2, according to the following reports by Mr. Ross:—

February 27, 1884.—From the point 0 a feeble auroral arc was observed extending from west to north-north-east, the intensity of which gradually increased. At the same time there appeared in the direction of Pietarintunturi, above the arc but not connected therewith, a sheaf of very intense rays, which moved rapidly westward and disappeared after passing the northern line. Not a single ray was visible in any other part of the sky.

March 2.—Messrs. Granit, Ross, and myself observed from this point an aurora which rapidly increased in intensity, and formed a corona as early as 8 o'clock. I immediately went to point III., in order that the luminous phenomena which might appear above the apparatus at Pietarintunturi might be observed from two points simultaneously. About 10.30 I perceived a very intense ray in the direction of Apparatus I., leaning at first a little to the east, but rising by degrees like a radiating sheaf, with a slight westerly direction. The phenomenon lasted from thirty to forty seconds. On telephoning to Mr. Granit, who remained at point 0, he replied that no luminosity was visible above the apparatus. Afterwards, and at short intervals, I three times saw a feeble ray in the same direction, but of different aspect. The ray, which was vertical, appeared of equal size and of a pale yellow colour. Although feeble it was very distinct. According to Mr. Granit no rays could be observed from point 0, either above the apparatus or around the mountain for a space of about 15° on either side, and on this occasion the moonlight was very bright, which, together with the intense aurora, rendered the observation of the luminous phenomena very difficult, and besides this, the distance from 0 to I. is 2·45 km., while from III. to I. it is only 1·56 km.

If any doubt remained as to the first observation, *i.e.* as to whether the rays were above the mountains or not, the second, taken on March 2, is quite conclusive. If Mr. Granit could perceive no rays at point 0, at a distance giving an angle of 15°

at two sides of the mountain, that merely proves *that the light was too feeble to penetrate a distance of 2·45 km.*, though it was visible at 1·56 km. The reflection of the moonlight was also stronger at point O than at III., because on this occasion the moon was nearly north-east.

It is not easy, I confess, to make a *résumé* of the results arrived at by the researches of the Finnish Expedition to Lapland concerning the electric currents of the earth and the atmosphere, chiefly owing to the circumstance that the materials are not as yet fully analysed, but the following may, however, be accepted as quite certain, as they are based on actual observations :—

The aurora borealis, which has long been a disputed enigma, is the result of an atmospheric electric current.

This auroral current can be measured, and, as a rule, studied, by the methods employed by the Expedition.

The "discharging-apparatus," or network of pointed conductors, used by the Expedition, has very often produced a diffuse light which gave in the spectroscope an auroral spectrum. Under very favourable conditions the light appeared in the form of rays above the apparatus.

With a Holtz electric machine the diffuse light may be *produced* under favourable conditions, and if it exists already it may be considerably intensified by the same means.

For the study of terrestrial electric currents a method has been found which, while avoiding all foreign influences, permits of the current being measured, both as regards absolute strength and as regards the exact laws which regulate it.

From these experiments it seems that the existence of a belt of terrestrial currents similar to the belt of auroral currents is very probable.

Helsingfors University

ON THE NATURE OF LICHENS

IN the *Journal* of the Linnean Society for December 12, 1884 (Botany) there appears a review of the "Algo-Lichen Hypothesis," by the Rev. J. M. Crombie, F.L.S., from the strongly conservative point of view of Nylander, on which I desire to make a few remarks as a critical student of Botany at large.

Mr. Crombie cites, as a fatal objection to Schwendener's hypothesis of symbiosis between the lichen proper and the alga forming its gonidia, that in other cases of vegetable parasitism "the hosts usually become speedily exhausted and finally perish, often involving in their death that of the parasite itself;" whereas here we have "a parasite exceeding in size and number of cells by many hundred times the nourishing plant which it invests." It is now over six years since I sent you, with reference to this very point, a brief note on the subject, which probably escaped Mr. Crombie's notice by its brevity, and of which I reproduce the substance. The essential elements of nutrition of a fungus, so far as we can judge from culture experiments, are as follows :—(1) *ash constituents;* (2) *nitrogen* in the form of nitrates, nitrites, or ammonia; (3) *carbon and hydrogen combined* in the form of tartrate, carbhydrate, or fat, &c. An alga requires only Nos. 1 and 2, deriving No. 3 by assimilation from the carbon dioxide of the atmosphere and water. The lichen hyphæ, aided by excretion of carbon dioxide, can dissolve the ash constituents, No. 1, from the substratum, taking them up by the rhizoids; the rain probably brings No. 2 in the form of traces of nitrates; No. 3 can only be formed by assimilation in the algal part or gonidia of the lichen. But, to obtain the carbhydrates, No. 3, there is no need for the hypha to penetrate the gonidium or to molest its protoplasm, as the algal cells have a cellulose wall, of which the outer layers undergo constant gelification and renewal. Into this it is that, as shown by Bornet ("Sur les Gonidies des Lichens," *Ann. Sc. Nat. Bot.*, ser. 5, xvii.) the hyphæ penetrate; and if they only lived on this, once formed, there would be no strain whatever on the resources of the alga. But, even if they stimulate an abnormally rapid cellulose formation, the injury need not necessarily be severe. We see oysters living well, though their shells are burrowed by the sponge Cliona; they produce new layers of shells far faster than when they are sound, but are otherwise uninjured.

An unlooked-for confirmation of these views is found in Johow's account of the Hymenolichenes (in Pringsheim's *Jahrbücher*, xv., part 2), where, "*in consequence* of the unusually close and perfect investment of the gonidia" by the hyphæ, the gelatinous investment of their cell-wall completely disappears. This is in marked contrast with the usual state of [illegible] figured by Bornet.

De Bary puts the case thus :—"With their growth (algæ) the assimilation of carbon dioxide persists in the plasm with its chlorophyll, and produces organic carbon compounds utilisable by the fungus. At the same time the hyphæ of the fungus ramify on and in the substratum, and take up the mineral pabulum required. These two processes supplement complement one another (*Vergleichende Morphologie und Biologie d. Pilze*, &c., 1884, p. 425).

It is further noteworthy that, if the growth in the gonidia is often favoured by their inclosure in the lichen thallus, their rapidity of multiplication by division is notably slow, while spore-formation, &c., remains in complete abeyance.

Mr. Crombie recalls the absence of algæ in places where lichens abound, *e.g.* "granitic detritus and boulders on the summit of lofty mountains." This follows from the fact that algæ alone cannot there obtain, unassisted, their pabulum of the mineral substances or ash constituents. The absence of fungi *alone* from these localities simply shows that they cannot live without their algal gonidia.

Mr. Crombie gives as an essential distinction between hyphæ of lichens and those of fungi the character of the cell-wall: "perennial, firm, penetrated by lichenin, [illegible] putrible, and insoluble in caustic potash in the former; very soft, with thin walls, readily putrifying on maceration, on the application of caustic potash, immediately becoming dissolved."

As regards the thickness and permanence of the cell-wall, it needs hardly to be recalled how much this character varies in different parts of the same fungus, and notably in corresponding organs of different members of the same group of fungi. Compare *Polyporus* and *Boletus*, *Schizophyllum* and *Coprinus*. As to the presence of lichenin, De Bary states (*op. cit.*, p. 97) that in at least three gelatinous fungi—*Hyalonema*, *Polystigma*, and *Hysterium macrosporium*—the hyphæ [illegible] on the application of aqueous solution of iodine, that is, give the "lichenin reaction."

As regards the alleged solubility of fungus hyphæ in caustic potash, I am at a loss to understand it, having, like most workers, been in the habit of using this reaction "for clearing" fungus preparations to demonstrate the presence of parasitic fungus hyphæ, which would be impossible if it dissolved them. I find no account of this solubility of fungal cell-walls in Sachs's meister's very complete "*Lehre von der Pflanzenzelle*," or De Bary's above-cited work.

A misapprehension on the part of the author is that "the Schwendenerian school have overlooked the [illegible] cortical layer" when they speak "as if only two elements entered into the structure of lichens, viz. hyphæ and gonidia." Undue, so far as it is true, to the general recognition by botanists that such pseudo-parenchyma as that composing the so-called cortical layer of lichens, of fungus sclerotia, &c., is an extreme modification of the hyphæ. But, far from being ignored, it is figured and described by Sachs ("Text-Book of Botany," (1st Engl. ed., Figs. 188, 189, and explanation), where he says "The upper and under cortical layers [of *Sticta*] also consist of hyphæ, which, however, . . . consist of shorter cells, closely united without interstices, forming a pseudo-parenchyma." This formation is also described by Bornet (*op. cit.*, p. 97, n. 1). De Bary writes (*op. cit.*, p. 436): "The hypha-branches which form the cortical layer ('Rindenschicht') are [illegible] without interstices, save in certain species of *Roccella*. The cells either recognisable as such, having the lumina of their mature cells evidently elongated and cylindrical, even though shorter than those of the medulla, or else they are formed of the same diametric rounded prismatic cells, giving the cortex the character of a pseudo-parenchyma, which is often extremely regular and neat ('*zierlich*'). . . . The structure of these cortical layers shows great similarity to that of many sclerotia."

In the latter half of the paper Mr. Crombie exposes at length the view that the gonidia originate in the cellules of the thalline and cortical layers,[1] and illustrates it by figures. In this no attempt is made to show the part played by the plasm in the process, an omission which is an implied censure of the inadequacy of the weapons, optical and [illegible]

[1] As regards his statement that "specimens illustrating the early stages of lichen growth appear to be unknown to the supporters of the [illegible] theory," it is only necessary to revert to Bornet's paper, p. 91

investigations on which the view is based.[1] chlorophyll bodies and plastids generally are of all kinds, and in view of the recent re- urt played by nuclei in cell formation, we had me allusion to these matters in a research regards the optical powers employed, two e. Cambridge was subjected to severe competition; a new University in the north of England was supplying considerable means of research; and before long it must be expected that the plans for a Teaching University for London would be carried out. It would be economical to make good provision while they were about it. The estimated sum of 30,000*l.* was as low as would provide suitable accommodation. The chief objections urged against the proposal were as to the magnitude of the sum in proportion to other requirements and to the funds at the disposal of the University. Prof. Humphry made a vigorous appeal to men of wealth, who might find in Cambridge many objects worthy of their munificence. Cambridge laboured under the double disadvantage of being poor and of being thought rich.

THE following courses of Lectures and Demonstrations in special branches of Physics will be given in the Physical Lecture Room and Laboratories of the Science Schools, South Kensington:—(1) Connection between Sound and Music. Six Lectures and Demonstrations by R. Mitchell, at 2 p.m. on February 23, 25, 27, March 2, 4, 6. (2) Certain Optical Measurements. Eight Lectures and Demonstrations by H. H. Hoffert, B.Sc., at 2 p.m. on March 9, 11, 13, 16, 18, 20, 23, 25. (3) Electrical Measurements. By C. V. Boys, A.R.S.M., at 2 p.m. on April 13, 15, 17, 20, 22, 24, 27, 29; May 1, 4. (4) The Chemical Action of Light. By Capt. W. de W. Abney, F.R.S., at 2 p.m. on May 6, 8, 11, 13, 15, 18, 20, 22. The above courses are open without fee to all second and third years' regular students of the Normal School of Science and Royal School of Mines, on their giving to the Registrar a written recommendation from the Professor or Lecturer whose classes they are attending at the time. The fee to others attending the courses are; for each separate course, 10*s.*; for all the courses, 30*s.* Such fees are payable in advance to the Registrar of the Normal School of Science and Royal School of Mines. These courses will only be given if a certain number of applications are made a week before February 23. Those intending to join are therefore requested to do so as soon as convenient. All the courses are open to women.

LONDON

Royal Society, January 29.—"On the Structure and Development of the Skull in the Mammalia. Part III. Insectivora." By W. K. Parker, F.R.S.

Although this paper is confessedly only a fraction of what is necessary to be done in this polymorphic order, it shows at least how difficult a group it is to handle. For the Insectivora are set in the midst of the other mammalia—low and high. They might be called the biological stepping-stones from the Metatheria to the Eutheria.

One thing can be done, even now, with our present fragmentary knowledge of the structure and development of the insectivorous types—we can assure ourselves that these types are immediately above the Marsupials, that they have the bats (Chiroptera) obliquely above them, that their nearest relations must be sought for amongst extinct Eocene forms, and that, lowly as they are, and arrested and often dwarfed to the uttermost (so that nature could not safely go further in that direction), they are rich in prophetic characters that have come to perfection in larger and nobler types.

I think it will not be denied that in the ascent of the types the Chiroptera are above the Insectivora, and, as it were, a sort of special "new leader" from that stock, and that the Insectivora are more or less transformed modifications of the marsupial type. I suspect that the existing Insectivora just yield the zoologist one of his groups of types classed together because he knows not what else to do with them; they are not a proper, clear, special branch or "leader" of the mammalian line-army. They form one group under one designation, just as the *poor* of this metropolis form a group; their special mark is simply lowliness; they differ *inter se* almost as much as the whole remainder above them differ. The higher forms, however, because of their elevation, can afford to be sub-divided again into order after order. If we could descend and see the transforming and newly transformed Placentalia of the Eocene epoch, then the morphologist and the zoologist would find common ground; the taxonomy of the latter, however, would be as useless as the titles and distinctions of modern society to some undeveloped race of savage men.

The best type of Insectivore for general comparison is the

hedgehog (*Erinaceus europæus*), as it shows the least suppression of parts, and the best development of that which is diagnostic, so to speak, of the order. In it the great investing bones of the skull are similar to those of the marsupial, but the nasal and squamosals are smaller, and the frontals are larger. In the hard palate there is a considerable relapse, as in marsupials, certain tracts of bone being absorbed, but it has no mesopterygoids, and only *five* vomers, yet the anterolateral pair are well developed. Moreover, the tympanic region has only one annulus, the outer bone; there is no separate os-bullæ. Instead of the latter there is a crescentic shell of bone which grows from the basisphenoid, greatly increasing the size of the tympanic cavity. In the endo-skeleton in front of the tympanic cavity there is a remarkable ridge of bone growing outwards from the alisphenoid. That ridge is the remnant of the alisphenoidal tympanic wing of the marsupial, and the shell of bone growing from the basisphenoid is the same morphological element as the separate os-bullæ, but it has lost its independence. The higher mammalian type is fully reached in the thorough freedom of the alisphenoid from the general cranial wall. This character, indeed, is intensified into the special diagnostic of an insectivore, for it lies almos, wholly outside the orbitosphenoid. Here the sphenoidal fissuret which in this case lets out the second branch of the fifth, but not the optic nerve—that nerve having its own foramen in the orbitosphenoid—is not a mere gap, but a *side passage*, or a sort of sphenoidal corridor, right and left. In these things the hedgehog is higher than the marsupial, but in some others it is lower, or more archaic. These latter characters, which suggest an uprise from a more general type than the existing metatheria, are—

(1) The development of solid hyaline cartilage in the pterygoid region, a remnant of the pterygo-quadrate of the Ichthyopsida.

(2) The presence of a persistent pituitary hole, which is connected with a curiously specialised structure only seen in typical insectivores, namely, a hollowing out of the basis cranii beneath the pituitary region.

(3) A third archaic character, not seen in the existing marsupials, is the huge relative size, long persistence, and separate distal ossification of Meckel's cartilage, so that in the embryo hedgehog, and even in the nestling, the primary lower jaw is as large as in fishes generally, scarcely excepting the Selachians.

The ossicula auditûs are typically Eutherian; we have lost the imperforate stapes or columella, the interhyal is very small or absent, and the malleus and incus are much like what we find in the higher mammals generally. The pneumaticity of the skull is much reduced: the olfactory region is almost double the relative size of that of a Marsupial. In the head of another family of the Insectivores, namely, the mole (*Talpa europæa*), there is much that is in accord with what is found in its distant relation, the hedgehog, but in it there are evident signs of degradation and of relapse into what is Marsupial in character. The nasal labyrinth is relatively immense, and the skull-walls below, laterally, and behind are as exquisitely pneumatic as in the flying Marsupial (*Petaurus*), the bird, or the crocodile. The swollen basis cranii, all air galleries within, is so excavated that the hinder sphenoid, both base and wings, largely helps the flat single tympanic to form the drum cavity. The pituitary hole does not exist, but there is a considerable pterygoid cartilage. The ossicula *in the adult* are normal, but a curious special character is seen in the ossification, in the young, three parts grown, of the sheath of the stapedial artery, which for a time holds the stapes in its place. It is, however, absorbed afterwards, but remains in the related genus *Myogale*. In nearly half-grown young moles the malleus is quite like that of the marsupials; it is an evident "articulare," with copious wild growths of bone, sub-distinct, which answer to the "angulare" and "supra-angulare" of a reptile or bird. This malleus in its articular part has two endosteal and one ectosteal bony centre.

Meckel's cartilage, long continuous with the malleus, is nearly as massive as in the hedgehog, and has a more distinct separate ossification in its sub-distal part, a long, independent, but temporary *hypobranchial bone*.

The mole shows a most remarkable development of the endo-cranium, which, twenty years ago, suggested to me that its skull retained unmistakable monotrematous characters. In large young of the *Echidna* and *Ornithorhynchus* the solidity of the chondrocranium is immense, like that of a *Chimæroid* Selachian, and the investing bones are thin and splintery. I have not made out the mode of ossification of the inner skull in those types, but in *spirit*, if not in the *letter*, the mole agrees with them, that is, in the great development and indep— of the inner skull. The opisthotic bone ossifies the ... petro-mastoid region, whilst the prootic bony centre ... its right place on the front edge of the cartilaginous cap... then runs away from it into the wall of the skull. Thus ... a large bony tract in the temporal region between the sp... and the large interparietal, which is not one of the ... ectocranial bones, but an endo-cranial bony tract overs... and yet imitating the true temporal bone or squamosal ... bone is represented by three separate centres in osseo... namely, the prootic, pterotic, and sphenotic, while ... auditory region is partly ossified by the epiotic and ... the epiotic is only sub-distinct in the mole. If I am ... I dive so far down for my illustrations, instead of being ... with what reptiles and birds would show me, my answ... these are often of no use for comparison, as they ... thoroughly specialised for their own mode of life as the ... malia generally, and are as completely, and often ... pletely, transformed from the original archaic type ... Thus the mole, like most of the Edentata lately described, ... suggests as the root stock of the Eutheria generally, ... supials (Metatheria), as we know them, but probably ... in which, in ages long past, the existing monotremes ... supials had a common origin. The shrew (*Sorex* ... represents another family of the Insectivores, the Soric... combines the characters of the mole and hedgeh...; ... peculiarities of its own that are manifestly due to ... many things are suppressed, as if there was not room ... a skull for their development. The pituitary hole ... and the pterygoid cartilage, but the tympanic ... alisphenoid and of the basisphenoid are gone. The ... does not show itself so unmistakably marsupial, and ... cartilage is slenderer. The sheathing alisphenoids are ... the squamosal is extremely small, low down, and ... jugal process; the jugal bone is suppressed. The ... is present, as in the mole.

So much for the British representatives of these ... the Insectivora—the Erinaceidæ, Talpidæ, and Sori... Mascarene Insectivora are so evidently related to each ... to suggest at once a common origin; these are the ... the largest of which is the Tenrec (*Centetes ecaudatus*) ... genera treated of in this paper are *Ericulus*, *Hemicen...*, *Microgale*.

These are almost typical Insectivora, but they agree ... shrews in having the jugal bone suppressed; they are ... marsupial than our native kinds. In these types the ... characters of the skull of an insectivore are combined ... remarkable marsupial tympanic wing to the alisphenoid ... os-bullæ is not free, it is merely an outgrowth of bone ... basisphenoid. The pituitary hole is present and in ... species the curious basi-cranial excavation; the optic ... also and the sphenoidal side passages are remarkably ... As in the genus *Phalangista* among the marsupials ... and *Talpa* among the British Insectivora, the ante... vomers are evidently suppressed, or have a very tempora... pendent existence: the postero-lateral vomers are rather ... as in the hedgehog. In the embryo the main vomer ... as large as in the embryo whale, and is curiously ... spongy. In nestlings this one primary azygous ... broken up into three: one, the largest, above, and ... below, sheathing it, as it sheaths, the base of the nasal ... Now this multiplication of the vomers proper is ... marsupial. It is unique, as far as I know, in the ... sub-division into secondary bony centres. In the Afric... tinental) family the elephant or jumping shrews (Macros... as illustrated by the largest forms, *Petrodromus* and *Rhyn...*, we have a curious mixture of marsupial or metathe... eutherian characters, so that they are aberrant as ... the marsupial characters are most remarkable. Thes... (1) the absence of an optic foramen in the embryo; ... alisphenoids scarcely overlapping the orbitosphenoid... tympanic wings of the alisphenoids are well marked, ... shells in the embryo; (4) large antero-lateral vomers ... postero-lateral vomers as large as in average marsupials, ... in many of them, meeting and uniting at the mid-line ... large distinct "os-bullæ," which makes a tympanic ... large as, and much like that of, *Petaurus* or *Phascolomys*. ... the high eutherian side we have, in the embryo, frontals ... as the parietals, and, strangest of all mammalian anomalies, ... a long *proboscis*, composed of thirty double rings of cartilage

The hair is allowed to …I here it is much cultivated, and …which are stiffened with grease and …ere are but slight traces of religion among the Wa-taita. They are afraid of spirits who are supposed to dwell in large forest trees, and perhaps for the reason that their dead are always buried in the forest. Their marriages are arranged first by purchase, but after the preliminaries have been settled, the girl runs away and affects to hide. She is sought out by the bridegroom and three or four of his friends, and when found is seized and carried off to the hut of her future husband. The Akamba, who live to the north of Taita, are a very roving, colonising people, and great hunters. One of the most interesting tribes are the Wa-tarata, who exhibit marked peculiarities in their language and ideas. They are of fair height, some of the men attaining to six feet. They frequently let the beard and moustache grow, and usually abstain from plucking out eyelashes and eyebrows. Circumcision is general. Marriage is a matter of purchase, but no sign of imitating capture seems to be practised here. They number about two thousand, and bear an excellent reputation among the coast traders for honesty and friendliness. Mr. Johnston described some of the chief characteristics of several other tribes with which he had come into contact during his visit to Kilimanjaro, and referred particularly to the languages spoken by the various peoples, one of the most interesting of which is the Masai, which has many characteristics not possessed by most of the other African languages.

Paris

Academy of Sciences, February 9.—M. Bouley, President, in the chair.—On a new disposition of the revolving mirror for the measurement of the velocity of light, by M. C. Wolf.—On the determination of the ohm by the amortisement method, by M. Mascart.—On the velocity of the detonation in solid and liquid explosive substances, by M. Berthelot.—On the epiphallum of some of the gasteropods, by M. H. de Lacaze-Duthiers.—Note on the skeleton of an extinct hyæna (*Hyæna spelæa*) discovered by M. Felix Regnault in the Gargas Cave, near Montrejean, by M. A. Gaudry. This cave hyæna appears to have been scarcely larger than the present spotted species, but the bones were thicker, so that it appears to have been a heavier animal. The author proposes to constitute it a distinct species, as *Hyæna crocuta*.—Remarks on the new volume of the annual series issued by the Observatory of Rio de Janeiro, and presented to the Academy in the name of the Emperor of Brazil, by M. BERLIN

Physiological Society, January 16.—Dr. H. Virchow, referring to the results of his investigations into the structure of the eye in different mammalia, communicated those which had reference to the zonula zinnii. He illustrated by diagrams the situation of this organ and the course of its fibres, set forth the various methods of examination, the efficiency of which he demonstrated by a series of preparations, and discussed the different views advanced on the subject of the canal of Petit and the ciliary apparatus. As the result of his researches he found that the zonula zinnii consisted simply of fibres, which at places where they were ranged closer to one another were connected by an intermediary substance, while at those where the fibres kept further aloof from one another no such intermediary substance was present.—Prof. Albrecht from Brussels, as guest, spoke on the morphological significance of the swimming-bladder of fishes. As was known, this bladder was either in open communication with the intestinal tube, or the connection between the two was obliterated, and in this latter case it might well be assumed that the communication in question had existed in earlier stages of development. Many naturalists were of opinion that the swimming-bladder was homologous with the lungs, which likewise represented a tube in communication with the intestinal tube—an opinion, however, decidedly opposed to the views of the speaker. For in all fish the swimming-bladder was placed supra-intestinally, or on the dorsal side, while the lungs are invariably situated infra-intestinally, or on the ventral side of the intestinal canal. If these two organs were homologous, the dorsal organ, in order to its transformation into a ventral, must, by some means or other, have made its passage around the œsophagus. The assumption, however, of either a right-sided or a left-sided passage, or, in fine, of a double division of the swimming-bladder, each of which had wandered downwards on one side, there to form together the two halves of the lungs, was a notion which laboured under difficulties and contradictions. Altogether, in the opinion of Prof. Albrecht, it was erroneous in any case to explain dorsal and ventral organs as homologous, and just as much so in the intestinal canal as in the brain. The swimming-bladder and the lungs were, on the contrary, rather completely heterologous organs. The best argument for the truth of this view was afforded by those fishes which possessed two bladders, a supra-intestinal and an infra-intestinal. Such a phenomenon would be absolutely impossible if these bladders were homologous. In point of fact, in the gymnodonts, diodonts, as well as tetrodonts, there were found a dorsal swimming-bladder, and, beside it, ventral air-sacs proceeding from the œsophagus, by means of which these fish were enabled to inflate themselves. These ventral air-sacs were homologous with the ventral lungs and heterologous to the dorsal swimming-bladders. There were, furthermore, fishes which, of the two protrusions of the intestinal canal, developed only the ventral, while the dorsal became absorbed. Such was the case in Polypterus, which possessed an infra-intestinal swimming-bladder, and in which, therefore, the homologue of the lungs was alone developed. There were, moreover, fish in which both protrusions became absorbed—the dog-fish, for example, which had no swimming-bladder whatever. An interesting support to this view of Prof. Albrecht's was afforded by the fact that, even in the case of mammalia in which the ventral protrusion of the intestinal tube had developed into lungs, remains of the dorsal swimming-bladder were pre[sent] in a rudimentary form. Such the speaker took to be the [fi]ficula of the œsophagus, a not uncommon pathologic occu[r]rence in man, which were always dorsal and occupying a po[si]tion opposite to the entrance into the larynx. These diverti[cu]la, according to the experience of surgeons, were not only i[n]dicative but also hereditary, a character which certainly witnesse[d] their phylogenetic significance. These dorsal diverticula of [the] œsophagus, which occurred only pathologically in man, [we]re a regular occurrence in another mammal, the cow. In [the]se therefore, among the mammalia, just as in diodonts and [te]trodonts among fish, were found both protrusions of the [in]testinal tube, the supra-intestinal and the infra-intestinal, ex[is]ting beside each other, the most indubitable proof of their hetero[lo]gy. Prof. Albrecht proposed calling the dorsal protrusion the [sw]imming bladder, and the ventral the vocal bladder.—Dr. [K]ossel had from pancreas extract obtained a new base, which belo[ng]s to the group of bases obtained by him from the contents of [an]imal and vegetable cells, guanidine, xanthine, and hypoxanthine. [In] an analysis of 75 kilogrammes of pancreas extract he had [ob]tained, besides guanidine and hypoxanthine, a hitherto unk[no]wn base, which he was able to separate from the two and [ob]tain in fine crystals. With hydrochloric and sulphuric acid [it] likewise gave fine large crystals. By reason of its occurrence [in] the pancreas, Dr. Kossel had called this new base "adenine." [Its] chemical composition corresponded with the formula $C_5H_5N_5$; it was, therefore, polymeric with hydrogen cyanide, and held the same relation to hypoxanthine, $C_5H_4N_4O$, as guanidine, $C_2H_5N_3O$, did to xanthine, $C_5H_4N_4O_2$. Later on he succeeded in authenticating the presence of adenine in the [li]ver, likewise, as also in yeast, so that this base, too, appeared to have a more general diffusion. Adenine appeared to have an important physiological significance, on account of its constitution. It had hitherto been assumed that urea must be derived from a cyanic compound, though such had not been able to be traced in the bodily tissues. Adenine, therefore, in consideration of its constitution, would seem to some relation to the formation of urea, a conjecture which further investigation might settle.—Prof. Du Bois-Reymond laid before the Society monstrous hoofs of horses and bovine animals sent from the Falkland Islands to the Physiological Institute, which, from their massiveness and the turning in of the horny tissue, would, by their appearance, hardly be recognised for the hoofs of horses and bovine cattle.

Messrs. MACMILLAN & CO.'S NEW BOOKS.

LADY BARKER ON WESTERN AUSTRALIA.

LETTERS TO GUY. By LADY BARKER (LADY BROOME), Author of "Station Life in New Zealand," &c. Crown 8vo. 5s.

The *Times* says:—"The 'Letters to Guy' demonstrate that the writer has a quick and observant eye, which suffers little to escape her in the shape of natural scenery or the characteristics of the people whom she meets. Bearing in mind that the letters are addressed to a boy in England, they are all that such letters should be—graphic, sparkling, and amusing. . . . Read in the right light—the light of frank, chatty, and familiar letters from a mother to her son—they cannot fail to be appreciated and enjoyed. We must take leave of Lady Barker's delightful and interesting little volume. It makes no pretensions to be a serious book of travel, but it cannot fail to please by the *naïveté* and frankness of its style. Moreover, to most readers in England who are unacquainted with the scenery of Western Australia, it will have an additional value because of its word-pictures of that distant colony."

NEW AND CHEAPER EDITION.

THE LIFE OF JAMES CLERK MAXWELL.

With Selections from his Correspondence and Occasional Writings.

By LEWIS CAMPBELL, M.A., LL.D., Professor of Greek in the University of St. Andrew's, and WILLIAM GARNETT, M.A., Principal of Durham College of Science, Newcastle-upon-Tyne

With Portrait and Illustrations. New Edition, Abridged and Revised. Crown 8vo. 7s. 6d.

"Those who desire to make the acquaintance of one of the rarest and most original spirits of our time will read the biography."—*Times.*

TWENTY-SECOND ANNUAL PUBLICATION

(Revised after Official Returns) of

THE STATESMAN'S YEAR-BOOK.

A STATISTICAL AND HISTORICAL ANNUAL OF THE STATES OF THE CIVILISED WORLD FOR THE YEAR 1885. Edited by J. SCOTT KELTIE. Crown 8vo. 10s. 6d.

"Everybody who knows this work is aware that it is a book that is indispensable to writers, financiers, politicians, merchants, and all who are directly or indirectly interested in the political, social, industrial, commercial, and financial condition of their fellow-creatures at home and abroad. All the information that could possibly be desired by politicians, merchants, and public speakers and writers relative to the Constitution and Government, the Church and education, the revenue and expenditure, the army and navy, the area and population, the commerce, industry, and trade of every civilised country in the world is to be found readily accessible within the small limits of this admirable Year-Book."—*Standard.*

MACMILLAN & CO., LONDON.

A MEDICAL NOVEL.

RLEY KINGSTON'S AUNT.

A Study of Medical Life and Experience.

EN OLIVER, F.R.C.S. Second Thousand. Crown 8vo, 6*s*.

ten by a physician, with a medical student for its hero, would deserve a few words of notice f it were of less conspicuous merit than this interesting volume. . . . The plot turns upon ncident, but it is well worked out, and the interest is well sustained until the mystery is fully e scene is laid in one of the best known of our medical schools of London, and old ave no difficulty in recognising the truth of several of the portraits which are incidentally om its technical interest, this book will secure attention by its vigorous writing, its many s of life and character, its clever incidental use of a picturesque and fading rustic dialect, ces and just compliment to some of the social traits of medical character; . . . with intimate knowledge of medical society, and a bright insight into some of the best sides haracter."—*British Medical Journal.*

titioner who wishes to renew the memories of his youth the book may be confidently companion of an idle hour."—*Medical Times.*

ke your flesh creep,' said the Fat Boy to the old lady at Dingley Dell. That is what Mr. f 'Charley Kingston's Aunt,' wants to do to his readers, and does very effectively in his there is much besides 'creepiness' in the book: cheery descriptions of old-fashioned n excellent 'interior' of a common lodging-house, a well-sustained tracking of a mystery, Suffolk talk by one who evidently knows it well. This single-volume story is one which Mudie's."—*The World.*

n has one of the most startling experiences ever accorded to a medical student. This e foreground of the story where the clever French mystery novelists put the murder. the tale reminds one a little of that of Mr. William Gilbert, who used to write such tories. This is in our opinion a favourable and flattering criticism."—*Daily News.*

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1200 or £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share being given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the new Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund,

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

MADAGASCAR AND FRANCE.

With some Account of the Island, its People, its Resources, and Development.

BY GEORGE A. SHAW, F.Z.S., London Mission, Tamatave.

With many Illustrations and a Map.

This book is of unusual interest. Mr. Shaw traces carefully the origin and history of the French claims in Madagascar, and enables his readers to estimate accurately both the French and Malagasy positions in the conflict. The chapters on the "Origin of the Malagasy," "Malagasy Civilisation," "The Present Civil and Religious State of the Malagasy," "The Fauna," and "The Flora of Madagascar" are full of attractive reading. The book has throughout the vividness of an eye-witness, and the accuracy of one who writes from first-hand knowledge, while a personal interest is given to much of it from the prominent part played by Mr. Shaw himself in the scenes described.

THE RELIGIOUS TRACT SOCIETY, 56, PATERNOSTER ROW, LONDON.

AUTOTYPE PHOTOGRAPHIC BOOK ILLUSTRATION.

ADVANTAGES.

1st. They present Faithful Representations of the Subjects.

2nd. Printed on the paper of the Book itself, mounting not required.

3rd. For Editions of 1000 and under they are cheap.

Employed by the Trustees of the British Museum and by the Learned Societies; also by many of the leading Publishers.

Amongst the Works recently done, or at present in the press, may be cited: Lady Brassey's "Tahiti"; Prof. Gardner's "The Types of Greek Coins"; Holtzapffel's "Practice of Ornamental Turning"; Audsley's "Ornamental Arts of Japan"; Lockyer's "Spectral Analysis"; Burgess's "Archæological Survey of India"; "Samuel Palmer: a Memoir."

Of this last work the *Athenæum* says:—"This book is admirably illustrated by fourteen autotype reproductions from lovely and characteristic sepia drawings."

be disposed of "in a very few minutes by simply destroying their unarmoured parts." It is upon this assumption that his charges against our ships and their constructors are mainly based. If it be correct, the Admiralty stand convicted of culpable neglect or error; but if it be incorrect, or very doubtful, then Sir E. J. Reed's charges are pointless and unjustifiable.

The question is one of most vital importance to the fighting efficiency of our principal ships of war; but how is it to be settled? It is not one with which mere theory or abstract science can deal: actual experiment can alone answer it. Sir E. J. Reed believes, and asserts, that such structures as the thinly-plated ends of our recent ironclads may be effectually destroyed in a few minutes, and that single shells may shatter large portions of them into fragments. He says:—"It is not a mere question of riddling the ends, but also one of blowing them up by shell fire: and how effectually they may be thus destroyed was shown at Alexandria, where a single shell, bursting against the unarmoured part of the *Superb's* side, tore a hole in it 10 feet by 4 feet in extent."

The apologists for this system of construction say, on the other hand, that if the area is increased over which the armour is spread, as would be the case if the citadels were lengthened, the thickness of armour throughout would require to be reduced; and the armour protection would therefore be less in the central portion of the ship which incloses the boilers, engines, and other essential elements of fighting efficiency. Many naval artillerists say, further, that unless the ends can be plated with the very thickest of armour, it is better to include everything which contributes to fighting power within the armoured citadel or below the armoured deck, and to make the ends as thin as possible. They argue that shells which meet with considerable resistance in penetrating armour of moderate thickness will shatter the ship's side, and make holes which cannot be stopped; whereas they almost invariably make clean holes through thin plating, and would, in the vast majority of cases, pass through the ship and out upon the other side. Such an instance as Sir E. J. Reed calls attention to in the case of the *Superb* would not, it is said, occur in practice more than once in one hundred times. The clean holes made by shells in thin plating can be stopped effectually and quickly by men stationed inside with shot-hole stoppers. These are made of india-rubber, and open and close like an umbrella. They are pushed out from the inside, and then pulled back and opened over the outside of the hole. The buoyancy and stability afforded by the ends can, it is confidently stated, be preserved by these means; whereas the damage done to any but the very thickest of armour plating would be so much greater that the holes made by shells could not be so effectually dealt with.

It is also pointed out that it is extremely difficult to strike a ship exactly at her water-line. The great majority of projectiles strike at some distance above it. If they are aimed too low they ricochet from the water surface and strike the ship above the water-line. It is most difficult to penetrate a ship exactly at her water-line; and if she is so penetrated, the holes may be much more readily and effectually stopped when the plating is thin than when it is thick. This is the argument which forms the answer to Sir E. J. Reed's charges.

Sir E. J. Reed says that "the reply to the British ... which are being made to depend for their flotation ... stability upon their unarmoured ends will inevitably ... small-gun attack," and he considers that even the ... from machine-guns may be sufficient to cripple ... This opens up a complicated question and one ... cannot be fully considered in all its details from a mere abstract point of view. There is obviously, however, ... limit to the effective use of small gun and machine fire, which is imposed by the necessity of protecting ... by armour if they are to fight at short range. If they are not protected by armour they can only be relied ... at long ranges; and even then they may as readily be placed *hors de combat* by the fire from the enemy succeed in penetrating, still less in destroying ... unarmoured ends of the latter.

These are points which experience alone can throw ... clear and definite light upon. Each party may continue ... advocate its own view with great show of reason, ... neither will convince the other till the effect of artillery upon such structures as the unarmoured ends of the ... in question has been thoroughly tested. In the meantime the public mind is only being bewildered and wearied ... the reiterated discussions of questions which can ... settled by mere argument or force of words.

A structure similar to the unarmoured ends of ... our ships might easily be built and placed afloat ... should then be fired at from various distances with ... different sizes. Valuable data might then be ... upon two crucial points: (1) the percentage of ... which would strike sufficiently near the water-line to affect prejudicially the buoyancy or stability; and ... nature of the holes that would be made; whether such ... are capable of being easily stopped from the inside, ... such as admit of no effectual stoppage, but practically constitute a disintegration or destruction of the ... This simple experiment might surely be made in such a way as to set at rest the discussion that has now been going on for so many years respecting the efficiency of the system upon which the safety and fighting power of our most powerful ships depends. Still, "water-line actions" would be the most favourable for such experiments, because it would obviously be more difficult to make good practice at a vessel's water-line in action—that is, in the ordinary circumstances, at sea, of rolling motion and the relative movements of the vessels engaged—than in a quiet and carefully arranged trial.

The only logical and effective answer that can be made to Sir E. J. Reed's letter is that which would be furnished by the results of experiments such as we have indicated; and that answer cannot be made too soon or too complete, either for the reputation of the Admiralty and of the Constructors of the Navy—who, to say the least, appear to be greatly in the dark respecting the practical merits of the system to which they are committed—or for the satisfaction of the public mind.

This question, upon the merits of which Sir E. J. Reed's charges must either stand or fall, is one which only Science can settle by experimental tests; but there is an important point underlying another assumption contained in his letter which may be discussed with advantage from a more abstract point of view. He says: "The Admiralty Director of Naval Construction, in the article 'Navy,' in the 'Ency

tannica,' lays down the following principle:—
st available approximate measure of the power
ps is their displacement or total weight. It
resents power of some kind.'" Sir E. J. Reed
principle, without reserve or qualification, and
t as an empirical method of determining the
hting powers of the ships of our own and the
vies.

g this principle in mind, as one accepted and
the Admiralty" he proceeds to compare the
nts of ten of the largest French ships recently
ten of the corresponding ships of our own navy.
ring result is arrived at:—"Looking at these
d bearing in mind the doctrine quoted—that
splacement means superior power, and inferior
nt inferior power—we here see that the Eng-
have been deliberately made inferior by our
ship by ship and squadron by squadron."

ot know what authority there is for saying that
ciple" is accepted and avowed by the Ad-
True, it is propounded by Mr. Barnaby, the
Naval Construction, in the latest edition of
clopædia Britannica"; but we have not heard

ther reasons, as compared with those of the
I could be disposed of by the latter "in a very
e."

sage displacement of the ten English ships re-
Sir E. J. Reed is 9,363 tons, and that of the
ing ten French ships is 10,470 tons. Applying
y's principle in the sense in which it is used
Reed—bearing in mind that "superior dis-
means superior power, and inferior displace-
or power," and that "the fairest available
e measure of power" is "displacement or
"—we arrive at the conclusion that the fighting
e ten English ships is rather less than nine-
of the French ships. Had their displace-
greater they would, upon the same prin-
been more powerful than the French
Sir E. J. Reed believes that, apart from
altogether, and because of the differ-
of construction employed in the two cases, the
s could be sunk by the French ships in a
nutes. The assumptions upon which the re-
uments are based are obviously inconsistent
her. One is that the English ships are infe-
of the French because their displacements
e other is that they are inferior because the
eir construction are not so wisely and effi-
med. Either one or both assumptions may be
the one has no necessary relation to the other.
ll compare Mr. Barnaby's present principle
pirical formula previously laid down by him
ning the comparative efficiency of ships of war. In the course of a lecture delivered in the Royal United Service Institution, in 1872, upon "Modern Ships of War," Mr. Barnaby put forward the following formula:—

$$\frac{A \times G \times H \times S^3}{L \times 100} = \text{comparative efficiency},$$

where A is the weight of armour per ton of ship's measurement, G the weight of protected guns and ammunition, H the height of battery port-sills above load water-line, S the speed in knots at the measured mile, and L the length of the ship.

Mr. Barnaby applied this formula to the seven ironclads named in the table given below. In this table we have placed, alongside the names of the vessels, a column which contains their displacements in tons. The next column contains their comparative efficiencies, as computed by the above formula; and the last column contains their comparative efficiencies, upon Mr. Barnaby's new principle that displacement is a fair measure of power. It will be seen that, according to the latter, the most powerful of these seven ships is the *Minotaur*, and the next the *Warrior*. The relative efficiency of the former vessel is three times greater than that given by Mr. Barnaby's previous formula; and the latter is nearly four times greater. The *Warrior* and the *Minotaur* are, according to this standard of comparison, the most powerful of the seven ships named; while the *Minotaur* would, upon the same principle, be classed as the most powerful fighting ship the British navy possesses at the present time—with the single exception of the *Inflexible*. In reality, however, the *Warrior* and *Minotaur* are the weakest and least efficient ironclads we possess; and are invariably classed as obsolete even in the most favourable estimates that are made of the fighting power of the British navy.

Names of ships	Displacement in tons	Relative efficiencies as computed by Mr. Barnaby's formula, $\frac{A \times G \times H \times S^3}{L \times 100}$	Relative efficiencies upon principle that power varies with displacement
Monarch ...	8,320 ...	149·8 ...	149·8
Hercules ...	8,680 ...	113·4 ...	156·2
Captain ...	7,900 ...	83·3 ...	142·2
Vanguard ...	6,010 ...	83·0 ...	108·2
Minotaur ...	10,690 ...	61·1 ...	192·4
Warrior ...	9,210 ...	44·5 ...	165·8
Defence ...	6,150 ...	10·9 ...	110·7

Nothing further can be necessary to show the fallacy, and the absolute inconsistency, of the views put forward at various times by Mr. Barnaby, respecting the standard by which the fighting power of a ship, or of a navy, may be judged. He has given no justification of either of the methods described; nor attempted to show that they are approximately reliable. The formula laid down by him in 1872 recognises that the fighting power of a ship of war is made up of various distinct and independent elements—that the amount of armoured protection, as represented by weight of armour; the power of the armament, as measured by its weight; the speed, and other qualities constitute elements of fighting power, which have different relative values, and which must be separately taken into account. We here find the value of manœuvring power, or handiness in turning, recognised by introducing the length of the ship as a divisor into the formula. This element of fighting power is assumed to

vary inversely as the length; so that, in similar ships, it would vary inversely as their displacements. In other words, so far as one element of fighting power is concerned, and that a very important one, the measure of its amount is not the displacement, as Mr. Barnaby now assumes, but the inverse ratio of the displacement.

The fighting power of a ship is thus composed of several diverse and independent elements; and there is nothing approaching to a consensus of professional opinion as to the relative importance of these elements. To assume that they all vary together with the ship's dimensions, or with her weight in tons, is in the highest degree delusive and absurd. The displacement of a ship measures her weight and nothing more. Whether that weight has been effectively and wisely employed in developing a high degree of fighting power, is an entirely independent matter; and one upon which the whole question of fighting efficiency depends. The statement that displacement "always represents power of some kind," merely begs the question. Of course it represents power; but such power is simply that of displacing water. It may represent that and nothing more, or it may represent in addition the possession of great fighting power, or of other desirable qualities. But the possession of such qualities, and the degree in which they will be developed, must depend entirely upon the skill of the designer—an arbitrary personal factor which is not always limited by the cubic feet of displaced volume that are placed at his disposal. Mr. Barnaby himself pointed out in the paper above referred to, that although the *Defence* and *Vanguard* have approximately equal displacements, the latter carried one-half more armour-plating than the former upon three-fourths of the weight of hull; and was so superior in manœuvring capability that she would turn completely around in four and a half minutes, whereas the former vessel required seven minutes to complete a circle. This difference in qualities, and superiority in fighting power, of the *Vanguard* over the *Defence* is absolutely undiscoverable by merely comparing the displacements.

All the comparisons we have seen of the fighting powers of modern ships of war and of our own and foreign navies, have been more or less vitiated by the arbitrary standards that have been selected as the basis of such comparisons. The displacement basis is unreliable and misleading, and furnishes no test whatever of fighting power. It would be extremely difficult to devise any simple standard by which the popular mind may be fairly impressed with the relative powers of our own and foreign navies; while for purposes of exact comparison or of technical discussion no such standard could be regarded as absolute. Before a simple standard or unit of comparison can be framed, which will be satisfactory or useful, naval officers, artillerists, and constructors require to agree among themselves about the relative importance of the various elements that make up the fighting power of a ship. The defensive values of armour-plating, speed, turning-power, and other protective qualities, and also the offensive values of the gun and torpedo armaments, the ram, speed, &c., require to be separately evaluated and their relative importance determined. If a general agreement could be arrived at as to the relative approximate values of each of these independent elements of offensive and defensive power, an empirical formula might be framed —such as Mr. Barnaby attempted with insufficient in 1872—which would fairly represent the gross efficiency of a ship. Till this is done, no rule can be devised which will indicate anything more than mere opinions of the person who frames it; while as in the case of Mr. Barnaby's present displacement basis, the application of the rule may be misleading degree which its framer could never have foreseen intended.

Sir E. J. Reed's letter to the *Times*, and the whole of the charges contained in it, rests mainly upon two of the two assumptions we have considered. That that the unarmoured ends of our present ironclads practically no protective value. This is a point which we have said, may be determined once and for scientific experiments. The second assumption is comparative efficiency of our own ships and those of powers may be approximately measured by merely paring their displacements. This proposition is and does not admit of any qualifying correction of depriving it of all specific meaning. A standard or unit of comparison which may be applied to the approximate determination of the fighting powers of war-ships and navies is great desired; but before such an one can be framed, sons who have to use our ships of war and to take into action, and those who are responsible for efficient construction, must come to some definite standing as to what the various elements of fighting consist of, and what are their relative degrees of ance; and to do so they must call in the aid of

PROFESSOR WILLIAMSON'S DYNAMICS

An Elementary Treatise on Dynamics, containing plications to Thermodynamics, &c. By Benjamin Williamson, F.R.S., and Francis A. Tarleton. (London: Longmans, Green, and Co., 1885.)

PROFESSOR WILLIAMSON is already known to the student by his excellent text-book the Differential, and of the Integral, Calculus, appearance in a new field of authorship is sure attention. We accordingly opened the present work expectations of a very high order. Not, of course, ations that much novelty of matter could be in an elementary work on a subject which has thoroughly threshed-out, but that possibly fresh and easier assimilability might be given to long facts and processes by some novel mode of presentation

In these expectations we have been disappointed Either the subject of Dynamics does not admit of ment superior to that which it has already received our authors are not destined to be the pioneers possible improvements. Our special reasons for statement we will give with some detail, but we begin with some general observations.

From the time in which Jackson, Lloyd, Wheatstone many others, introduced continental methods average Honour-man; through the period of Earnshaw Pratt, Wilson, Tait and Steele, Griffin, Walton, the Parkinson, Bezant, Routh, &c., of the present there has been a plethora of treatises in English various parts of elementary Dynamics. Some of

were robust, and showed considerable vitality, others sickly and short-lived. But, bad or good, among them they have practically exhausted the resources of the subject, so far as the theorems presentable to a beginner are concerned. The only ringing of the changes has been in arrangement, modes of presentation, and proofs.

But from the books of the future, some of which, at least, we may expect to see starting into existence in the present, we naturally, though perhaps vainly, look for something higher and better than this. We now have elementary treatises on the various branches of mathematics required in Dynamics (two, in fact, due to Prof. Williamson himself) so much superior to any that existed even twenty years ago, that we no longer require to have intricate steps of ordinary differentiation or integration introduced into a text-book of that subject. What we require may be summed up in two words, *Foundation* and *Arrangement*. To these must, of course, be added, as a requirement in every scientific treatise, *Consistency*.

The foundations of the subject, in by far the best form in which they have yet been presented, were given by Newton. He expressly states, before proceeding to give his second interpretation of the Third Law of Motion, that (so far) he had been giving principles generally accepted among mathematicians. But we can barely imagine the effort which must have been made by that transcendent genius in extracting such simple and yet all-comprehending statements from the portentous verbiage of even the most able of his precursors. Step by step, in Britain, Newton's system was forsaken; one of his Laws was split up into fragments, another ignored and its place supplied by gratuitous additional Axioms; till at last the monstrous process culminated in the adoption of Duchayla's so-called statical *Proof* of the Parallelogram of Forces. Thus everything was ripe for Thomson and Tait's reintroduction of the grandly simple system of Newton. The results of this step have been alike remarkable and important. These authors also introduced, after the example of Ampère,[1] the notion of separating the science of motion in the abstract (*Kinematics*) from that of motion of matter:—thus lightening the student's work, in Dynamics proper, to at least as great an extent as it is lightened by his previous study of integration and differential equations.

Now, in the book before us, these improvements on the text-books of twenty years ago are only partially adopted. Kinematics is not made a strictly preliminary study, but inserted in detached fragments. The exploded "statical measure" of force haunts us all through the book, sometimes leading to extraordinary results. Thus, opening at p. 30, we find the following passages, in which we have italicised a few words:—

"**Acceleration varies as Pressure.**"

"This equation enables us to determine the velocity generated . . . by a constant force . . . whenever the *pressure* which measures the *force* is known, and also the *weight* of the body."

"Thus a force which is capable of supporting a weight of 112 lbs. is called a force of 112 lbs."

". . . the same *effort* which would project a small stone to a considerable distance will move a large one but slightly."

[1] Ampère has never, to our knowledge, received the credit due to him for much of his best dynamical work:—*e.g.* the u, θ equation of central orbits.

Here we see, at a glance, the effects of want of system Pressure, Force, and Effort are used as completely synonymous and interchangeable terms. Now the first term has a perfectly definite meaning in science (introduced without definition or warning by our authors in § 290 of the book, to the utter bewilderment of the reader fresh from p. 30), and it means something differing from force in exactly the same way as a linear inch differs from a cubic inch. As to the Effort exerted in throwing a stone, we imagine that, if employed at all in scientific language, it would signify properly the work done, not the force applied; the two things differing as a square foot does from a linear foot. Of course our authors do not require to be told this, but why muddle the student by giving him slipshod information which he must *unlearn*, if he is ever to make progress?

On the opposite page (31) we find:—

"If a uniform pressure [force] of 3 lbs. [weight] produce a velocity [speed] of 10 feet [per second] in the first second, find the weight [mass] of the body acted on."

The insertions are ours, made with the view of showing how the question ought to be stated unless there is to be complete confusion of nomenclature.

Since Clerk-Maxwell published his admirable little book on "*Matter and Motion*" there has been left no excuse whatever for a misuse of the word *Velocity*. The adoption of Hamilton's Vector ideas effected an immense improvement in all these elementary matters. Yet we not only find constantly, in the book before us, this confusion of speed and velocity, but something even more grave, of which one example appears in the above extract. This is the use of the word "velocity" in the sense of so many units of length. See, for instance, pp. 28, 29:—

"'In what time will a falling body acquire a velocity of 400 feet?'

"'If one minute be taken as the unit of time, what should be taken as the value of g?'

'*Ans.* The velocity per minute acquired in one minute by a falling body.'"

Now, what on earth is a "velocity of 400 feet" or a "velocity per minute"? To make the first statement intelligible we must add "per (specified unit of time)"; and for "velocity," in the second statement, we must read "velocity in feet"; or, preferably, "speed in feet." The "per unit of time" is already present on *this* occasion.

Under this category we must quote the truly sensational heading of § 19:—

"**Relation between Velocity and Space,**"

for this is also obviously based upon the above erroneous designation of "velocity" as so many units of length.

In p. 124 we find:—

". . . time becomes a necessary element when we come to compare the *efficiency* of different agents. For instance, if one agent . . . performs an amount of work in one hour which it requires another five hours to accomplish, the former is said to be five times as efficient." [The italics are in the text.]

But, turn to p. 438, and we read:—a heat-engine being now the "agent":—

". . . the ratio of the heat converted into work to the heat drawn from the source is called the *efficiency of the engine*." [Again, the italics are in the text.]

It appears from this, as from a former example, that it is necessary to take the same word in two perfectly different meanings according as it is met with in the first (or ordinary dynamical) part of the book, and in the later (or thermodynamical) part. Such at least is the case with the two specially important terms, *Pressure* and *Efficiency*.

It is perhaps hypercritical to call attention to peculiarities of expression which, however they may puzzle him, can scarcely mislead the student. Else we might ask why (p. 8) a point is "*animated* by any number of velocities," or "*subjected* to any number of simultaneous velocities," or why "additional velocity" is said in contrast (p. 12) to be "*received*."

We have marked at least a score of places, in addition to those already noticed, in which the same or similar confusion occurs:—and yet we have *read* in all only about a fourth of the book here and there, having glanced over the rest much more hastily. But it is enough to have said, while illustrating our remarks by simple instances, that this is certainly not a book for beginners, nor for any one whose hold of the exact meaning of scientific terms is precarious:—though it may be consulted without danger (scarcely, we should think, with actual pleasure) by a student who, already soundly educated in the *principles* of Dynamics, desires to get a rapid and condensed *résumé* of their development by mathematical methods.

The principle of dual authorship rarely works well in practice. One of the authors of this book invariably speaks of *Centre of mass* (or of *inertia*) of a body, the other as invariably of *Centre of gravity*. And their responsibility has been so thoroughly divided, that *neither* of these terms is defined, so far as we can find (even with the help of the Index), anywhere in the volume. Again, one of the authors seems to have been always on the look-out to put in a little bit of Kinematics wherever he had a chance. And surely a third must have been at work, whose function was to stick in some sections on the *Rotation of a Rigid Body* (p. 92) between the sections on *Circular Orbits* and those on the *Simple Pendulum*.

The extraordinary *Olla podrida* of Schell is one of the authorities mentioned in the *Preface* as having been largely borrowed from. The book would certainly have been very much better had that work been let alone; though no work more richly deserves to be plundered in its turn than does that of Schell, who simply adopts (and too frequently distorts) whatever pleases him.

OUR BOOK SHELF

Les Organismes problématiques des Anciennes Mers. By the Marquis de Saporta. (Paris: Masson, 1884.)

THE views expressed in Saporta and Marion's "Evolution des Cryptogames" (reviewed at length in NATURE, vol. xxiv. pp. 73, 558) as to the origin of certain markings commonly met with in palæozoic rocks, has led to a long discussion in which many have taken part, the chief champions on either side being Dr. Nathorst, the distinguished Swedish botanist, and the Marquis de Saporta. Dr. Nathorst maintains that they are tracks left by moving or burrowing animals or other inorganic markings, whilst Saporta holds to his original opinion that very many of them are casts of primæval *algæ*, of kinds now extinct. Nearly all of these markings are in bas-relief on the under surfaces of slabs as if they were moulds of prints or impressions traced in the ancient muds, thus at first sight greatly favouring Nathorst's view of their origin. Saporta demonstrates on the other hand that this is a by no means uncommon mode of fossilisation among undoubted plants, and when we reflect on the composition of algæ, we shall see that scarcely any other mode of fossilisation among them is possible. A leathery olive green sea-weed lying on an oozy mud would cause an indentation, and if subsequently covered up, would keep the old surface free from contact with the fresh mud, until it might, under favourable conditions, have become sufficiently hardened to retain the impression. The sea-weed, as most sea-weeds do now, if left in water or fresh mud, would eventually completely dissolve away, leaving no perceptible organic trace of its presence. The cavity thus left would be filled in at last by the overlying mud, and either a cleavage plane would remain, following the contour of the under side of the weed, and marking its former presence. Sometimes, though rarely, the sea-weed might not decay until a cleavage plane had been established around its entire circumference, without leaving the smallest trace of its internal structure, as we often find is the case with far more resisting cryptogamic stems in the older rocks. This Saporta finds is the case with the Bilobites, one of the most vexed of all the "Organismes problématiques," and he relies with good reason upon their occasional occurrence in this condition and on their reticulated structure to support his contention that they cannot be mere worm tracks or burrows, and that in point of fact they can be naught but the impressions of primæval algæ. J. S.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance of communications containing interesting and novel facts.]

Civilisation and Eyesight

MY attention has only recently been called to a communication from Lord Rayleigh, which appears in NATURE for the 12th inst. (p. 349), and on which I crave permission to make a few observations. Lord Rayleigh questions whether the eyes of savages, "merely as optical instruments," are greatly inferior to our own; and suggests that any superiority which savages possess may depend upon "attention and practice in the interpretation of minute indications." He explains that "the resolving power of an optical instrument is limited by its aperture," and then proceeds as follows:—

"With a given aperture no perfection of execution will confer the power to resolve double stars, or stripes alternately dark and bright, beyond a certain point, calculable by the laws of light from the wave-length of light. With sufficient approximation we may say that a double star cannot be fairly resolved unless its components subtend an angle exceeding that subtended by the wave-length of light at a distance equal to the aperture. If we take the aperture of the eye as one-fifth of an inch, and the wave-length of light as 1-40,000th of an inch, this angle is found to be about two minutes; and we are forced to the conclusion that there is no room for the eye of the savage to be optically superior in resolving power to those of civilised physicists, whose powers approach at no great distance the theoretical limit as determined by the aperture."

I understand this to mean that optical conditions limit the resolving power of the eye to objects which subtend a certain angle of about two minutes, and that civilised physicists approach this theoretical limit at no great distance.

With great submission to the high authority of Lord Rayleigh, I venture to question whether we have any data from which to draw conclusions with regard to the possible optical powers of the eyes of the human race. We should probably fall into grave error if we were to argue from the reduced eye of Listing

or even from the eyes of the small number of persons whose visual function has been minutely tested, to the properties, as optical instruments, of the eyes of mankind in general. "La position," writes Helmholtz, "des foyers, des points principaux et des points nodaux de l'œil est assurément soumise à des variations individuelles assez importantes, puisque la plupart des mensurations de l'œil et de ses diverses surfaces réfringentes présentent, chez différents sujets, des différences plus grandes qu'on ne paraissait devoir les attendre pour un organ dont les fonctions semblent réclamer une si grande exactitude de construction."

As a matter of fact, the theoretical limit of resolving power assigned by Lord Rayleigh, to which he tells us that civilised physicists have "approached," is one which civilised physicists have considerably exceeded. The mean of twelve observers, as quoted by Helmholtz, gives resolving power under a visual angle of 101 seconds; and this mean is reduced by two cases in which the angles were 124 and 147 seconds respectively. The minimum was 51 seconds, the most frequent angle was about 80 or 90 seconds. The commonly accepted standard of normal vision among civilised people is satisfied by deciphering letters the parts of which subtend visual angles of one minute, while each letter as a whole subtends a visual angle of five minutes.

I cannot say, however, that I think any such tests are very material to the issue. The eyes of civilised physicists, or of such of them as have undertaken practical research in physiological optics, are probably very highly cultivated, and I doubt whether resolving power, which must depend chiefly upon the functional activity of the central depression of the retina or, in the case of stars, upon the functional activity of the zone which immediately surrounds the yellow spot, furnishes any accurate test of acuteness of vision in the sense in which I employed the phrase.

Assuming the civilised man and the savage to have eyes of precisely equal optical value, the latter might yet possess an acuteness of vision greatly in excess of that of the former; and this excess might be due to conditions of the percipient elements of the retina which, in the case of the savage, permitted the optical powers to be utilised to the fullest extent. The savage might have greater sensitiveness to variations of light, greater sensitiveness to colour, and acuteness of vision over a larger retinal area. All these advantages might be conferred by better formation or higher development of the retina, and such higher development might at once be promoted by exercise and handed down by descent. I support the "commonly-received view" that the vision of savages is more acute than that of civilised men, because this view seems to me to be established by abundant testimony, and to be in perfect harmony with physiological knowledge. I feel very strongly that the conditions of town life are unfavourable to the evolution of the eye and favourable to its involution or degradation; and I believe that a moderate amount of attention might greatly modify these conditions, and might do for the eyes what is done by athletic games and exercises for the muscles.

With regard to the improvement of Lord Rayleigh's own vision, in a dim light only, by concave glasses, I think his Lordship cannot fail to see that the case, as stated, does not contain all the data which would be required in order to arrive at an explanation of the phenomenon.

R. BRUDENELL CARTER

IN a short article on Civilisation and Eyesight which appeared in NATURE of February 12, Lord Rayleigh expresses the belief that the greater visual acuity of savages "is a question of attention and practice in the interpretation of minute indications" and is not ascribable to any possible inherent superiority in their eyes, regarded simply as optical instruments. With this conclusion probably most who have had opportunities of testing the sight of uncivilised races or read the account given by those who have undertaken such examinations, will agree. The same difference in making more or less out of an imperfect retinal image is met with in different individuals with the same degree of short sight, and otherwise subjected to similar conditions according as they have or have not been in the habit of resorting to constant optical correction of their defect. Such a cerebral elaboration of the retinal image, as it might be called, constitutes also probably the main reason for the difference between the visual acuity of children who have only just learnt to read the letters of the alphabet and adults, which our ordinary tests so frequently show.

The question of the increasing prevalence of short sight has for a considerable time been the subject of much investigation and speculation in Germany, the results of which have been in many cases to give rise to predictions of rather an alarmist tendency. These, again, have led to legislation in the shape of regulations with respect to school appliances which might meet the theoretical requirements of the most energetic and influential agitators. It is to be hoped that, as the question is now being brought forward in this country, it will be viewed in a more comprehensive manner. The numerous statistics from German schools have shown that the proportion of short-sighted boys continually increases from form to form, and from this fact it is very generally argued that the continued use of the eyes for the perception of near objects is the essential if not the only factor in the production of short sight. This view appears, again, to be supported by statistics which allot the largest proportion of short-sighted individuals to those branches of industry or those pursuits which constantly call for near vision. Two points, however, appear to be forgotten, or at all events fail to receive sufficient consideration, in arriving at such a conclusion. In the first place, there is an undoubted tendency to increase in the degree of short sight with age alone up to the period of cessation of growth. This has been shown to be due to the elongation of the antero-posterior axis of the eye, which carries the retina further and further from the principal focus of the dioptric media, and is in the vast majority of cases no more a disease than is the attainment of a greater than average height by a certain number of individuals. It is merely a type, and as such is governed by the laws of heredity. A small proportion of cases of short sight are, however, due to disease. These differ from the ordinary cases in that they are seldom hereditary and are not more frequently present in the learned than in the absolutely illiterate classes, besides which the pathological changes to which they are due can often be detected with the ophthalmoscope. The second point which has to be taken into consideration is how far the greater proportion of short sight amongst literary men, or artisans whose daily work necessitates close vision, is actually due to their occupation, or depends on the circumstance that, being originally short-sighted, they have drifted into pursuits which are more attractive to them, owing to their not being able to enjoy out-door work or sports to the same extent as others whose eyes are more fortunately focussed. That the choice of a life-occupation is often influenced by the condition of the sight is a matter of every-day experience, and it would be interesting to have statistics showing to what extent this occurs in the case of myopia. Further, as a man's circle of acquaintance is, for the most part, amongst individuals having similar interests in life, intermarriage in myopic families must frequently occur, and would tend to perpetuate, and perhaps increase, the defect. In savages, on the other hand, where the great principle of the survival of the fittest is not frustrated to the same extent as among civilised races, everything would evidently be against the perpetuation of the myopic type. The question comes to be, then, Is not the absence, or comparatively great infrequency of short sight amongst savages due rather to the requirements of such races being antagonistic to the circumstances which would be most likely to perpetuate the myopic type, than to the fact that young savages are not subjected to compulsory education? The pages of NATURE are perhaps hardly the place to develop very fully a question of this kind; suffice it to say, therefore, that the conclusion which such reflections, as well as the result of every-day examination of cases of short sight, appear to justify, is, that *the increase of myopia is due mainly to the perpetuation of a type through the requirements of civilisation*, and, though not a disease in the ordinary sense, it is desirable to attempt to check its progress. This will assuredly not be an easy matter, but it is not likely to be much influenced by such school reforms as have been introduced into Germany.

Lord Rayleigh mentions, as an interesting subject for further investigation, the slight myopia which he finds not uncommon when the light is lowered in a room, until objects begin to be indistinctly seen. He finds, *e.g.* that though in a good light he sees rather worse with a concave lens of 36 inches focus than without it, yet, when the illumination is diminished, the same lens increases his visual acuity. Altogether, the influence of illumination on visual acuity, and the relation between light-sense and form-sense, are points which have not yet received adequate attention. If the phenomenon described by Lord Rayleigh be really one of short sight occurring under the circumstances mentioned, it is evident that it can only be due to involuntary accommoda-

tion for a nearer point than that on which attention is directed—a kind of spasmodic myopia, and, as such, would disappear when the power of accommodation was paralysed by atropine. On the other hand, it may not be myopia at all, the improvement given by the weak concave lens being perhaps due to the contraction of the pupil, which would occur along with the accommodation necessary to neutralise the effect of the glass. If this were the case, the improvement would also take place by the use of a suitable diaphragm held in front of the eye. Still another possible explanation suggests itself, viz. that the new dioptric combination made up of the concave lens and partially accommodated crystalline might introduce conditions of chromatic and spherical aberration which were more favourable to distinct vision. The disturbing effects of such aberration are probably greatly neutralised by the arrangement of the retinal elements, but the degree of the neutralisation is, not unlikely, dependent on the amount of absolute and relative illumination of contiguous elements.

The Fall of Autumnal Foliage

THE paper by Mr. Sorby in NATURE for December 4, 1884 (p. 105) opens up an unpursued inquiry into the cause of leaves falling in autumn. While Mr. Sorby has had his attention drawn to the subject by looking at the actual trees and leaves "of the fine display of autumnal tints which we have lately seen" in England, there is much of both positive and negative evidence to be drawn in two extreme directions—the tropics and the pole.

Being, in the year 1881, home from India, where, it is not necessary to say, nearly all the trees retain their green foliage throughout the year, the writer indulged in a long curiosity to see the counties of Caithness, Orkney, and Shetland He went there with reference to the luminosity, which reaches its maximum in them for Great Britain, and is very marked and exceedingly striking and beautiful as a feature all over the north of Scotland in the month of June, when it is daylight all through the hours of night, sufficiently clear for reading distinct print at twelve o'clock midnight.

A peculiarity of Caithness and the Orkney and Shetland Islands is that no forest-trees can be got to grow. Setting on one side a remark "that it was because nobody had tried," the suspicion had already occurred to my mind that there must exist some other causes than those usually asserted—the high sea winds, bleakness in winter, and extreme cold—for this want of trees.

Any one who has been much in the north of Scotland, and is at all acquainted with the optical sciences, cannot fail to have noticed the immense amount of polarised light there is from the sky; almost all the diffused daylight, except for an hour or two in the middle of the day, being plane or elliptically polarised.

The attention of readers of NATURE may with advantage be specially directed to the possibility, from the phenomena of the north, that leaves fall in autumn from trees growing above a certain latitude—about 30°—through loss of vitality in the more or less highly polarised light.

The first thing a traveller from India notices in Alexandria is the American fall of the leaves in the Grande Place, or, as a fellow-passenger once put it, pointing to these, "It is here trees first become deciduous." It is worth being remarked that, not until reaching Cairo or Alexandria, can sun-protection be done without.

So far Mr. Sorby has to refer to the action of light in the last resort, as he says, with regard to leaves, "slight frosts reduce their vitality in such a manner, that the chlorophyll is changed by the action of the light into a red product."

Chlorophyll is composed of carbon, hydrogen, oxygen, and a trace of iron. Chemically it is $C_{18}H_{30}N_2O_3 + O_{18}$, resulting from the action of carbonic acid and ammonia on a fat, $C_8H_{14}O$, under the influence of light, as given by a different authority; but the composition of its products and combinations have not been traced. Still there is almost every constituent of the animal frame present except the earthy salts, and it must be a substance very sensitive to rays of light, or to what light probably is, electro-magnetic forces.

The weakening of the plant is supposed by Mr. Sorby to have occurred, for the leaves of a tree to have lost the vitality which counteracted the chemical degradation of the chlorophyll. Now in India or Ceylon, if a stalk were injured, the leaves would wither into brown. Trees remain, however, when in a constantly green, the leaves dropping off gradually one by one almost, and are immediately replaced. Indian leaves of course are much thicker, and more of the texture of parchment than those of foliage in European countries, and the phenomena of change can be studied in evergreens without going there, the observation merely serving to draw attention that might otherwise be given to the matter.

The Rothamsted experiments of Sir J. B. Lawes and Dr. Gilbert, F.R.S., bear closely on the question. They found (Session 1880, address) that plants assimilate chlorophyll not only during but a small portion of the year, but the action is limited to the hours of daylight, while during darkness there is rather loss than gain. The experiments, however, both there and in Norway by Prof. Schübeler, were made in ordinary unpolarised solar or electric light.

On the other hand, in India the light is intense owing to tropical position, and, from the altitude of the course of the sun very slightly polarised. It is only for an hour at dawn and another hour of sunsetting that the Indian is at all the case of daylight that it is in England. It accords with the Rothamsted and Norwegian experiments under the continuous exposure of vegetation to daylight and electric illumination during the night that the trees in India are large and evergreen. Of course in time leaves have done their work and fade, but as they have not been unfolded simultaneously, they drop off gradually in batches.

Where, accordingly, the light is polarised, trees are scarce or absent, mown by a swathing light; and in the tropics, where there is little polarisation, they are luxuriant, and green all the year round.

This is not inconsistent with fact. To begin with, the polarised light has half the intensity of ordinary white light, the set of vibrations at right angles to the plane of polarisation being absorbed in the reflecting matter of the sky. Moreover circularly or elliptically polarised light must largely predominate, judge from the metallic glow there is on the Pentland Firth, Orkney, and Shetland in midsummer, and what effect circularly polarised light has on the assimilation of carbon in the formation of plants and decomposition of chlorophyll is unknown.

At any rate, Caithness, and the northern islands have a number of hours in the daytime of a wintry darkness and scarcely any light in the summer months and its long day which is not polarised. From this cause, which could in the latitude their winter be put in arithmetical units of force, combined with cold winds and a thin soil, without alluvial deposits and on stone, it is no wonder that, though the inhabitants are strangers to the pathos of the fall of the leaf, the Caithness landscape, and the sward and heather of Orkney and Shetland are lustrous day and night with polarised light, and have autumnal foliage.

India, January 22

Erosion of Glass

IN reference to the letter of Dr. Ord in last week's NATURE glass is by no means proof against the action of either acids or alkalies, indeed its resisting seems to depend merely on its colloidal, at any rate non-permeable, nature. It may be generally known that water alone very rapidly acts on glass, especially when it is in a finely divided state, extracting alkalies and silica in quantity. It would be rash to put the action of substances on glass to "molecular coalescence," the exclusion of chemical action, or under the idea that hydrofluorine are necessary to etch glass. Alkaline salts, especially phosphates, act, either wet or dry, very vigorously on glass. One class of salts, the potassium salts of phenol sulphonic acids, have been noticed to literally tear a glass bottle in pieces in crystallising out of an acid solution. Ordinary gum is slightly acid in reaction; but the ordinary mechanical action of swelling and then contracting is probably quite sufficient to cause abrasion or etching, especially with soda-glass. This kind of mechanical action is often noticed in the distillation of organic substances which solidify at a high temperature, the whole interior surface of the retort being torn off and cracked in all directions.

esfield Rectory, Essex, February 17

Fullers Earth as a Filter

IN the *fuller's earth* is dug from the Bedfordshire green-sand it is held in much repute for its efficacy in removing impurities from turbid water.[1] In addition to the other uses to which it is here applied, dealers take it around through the fen countries, and dispose of it for clarifying the peaty water,[2] often the only supply obtainable in those districts.

I shall esteem it a favour on the part of the readers of NATURE residing on the Greensand or Oolites of the southern counties to notify if these filtering properties of the Bedfordshire fuller's earth are in any way unique—in so far as they appear withheld from that of other places?—as at Reigate, Bath, &c., where fuller's earth is known to them to be dug.

Bedford, February 23 A. G. CAMERON

The Boomerang in India

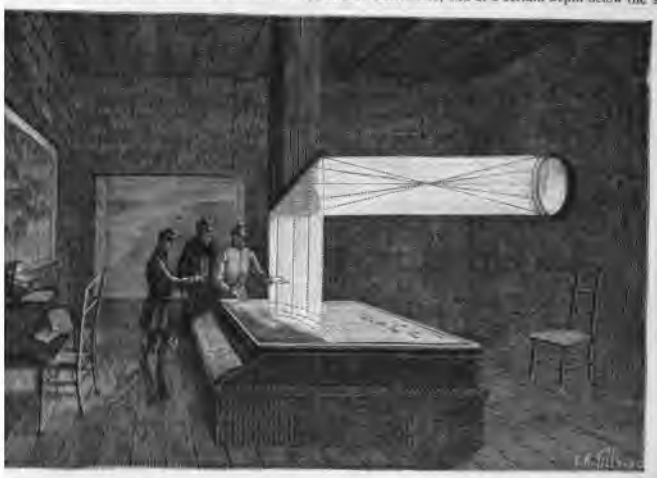
IN Gustav Oppert's work "On the Weapons, Army Organisation, and Political Maxims of the Ancient Hindus," the boomerang is mentioned as being among the weapons, especially in Southern India, and made of various materials—iron, ivory, and wood. Are any specimens to be found in our museums here, or would any private persons who may happen to possess any, kindly allow me to inspect them?

ARTHUR NICOLS

LA CAMERA OBSCURA IN TORPEDO WORK[1]

At the time of the last Austro-Italian war, in 1866, the Austrian Government made the greatest efforts to
t its harbours from an attack of the Italian fleet.
does were placed in great numbers in the harbours,
and the greatest vigilance was enjoined on all the commandants of such places.

The accompanying illustration represents a novel application of the camera for use at the observing or firing post of a party belonging to the military telegraph. The torpedoes are placed along certain concentric lines, very close to each other, and at a certain depth below the surface of the water, no sign of their presence being appa-
A metallic wire connects each of them with a post
rvation situated on the coast at a point sufficiently
d to permit of the port being seen. According to
own optical laws, an image of the port is formed
glass. Black points marked on that image indicates the exact position of each torpedo; these points are all numbered, each number corresponding with that on a particular key of a keyboard. To press one of these keys with the finger is sufficient to place the corresponding



[1] From *La Nature*.

torpedo in communication with an electric battery, by means of a metallic wire which connects it with the port, and so cause an explosion.

THE CONTINUITY OF THE PROTOPLASM IN PLANT TISSUE

THE translation of Dr. Schaarschmidt's paper in a recent number of NATURE (January 29th, 1885) gave those who, like myself, are unable to read Hungarian, full details both of his researches and views, and as one much interested in the subject of "the continuity of the protoplasm," I should like to be allowed to make a few remarks upon it.

To refer first of all to a matter of minor importance with reference to sieve-tubes, I see that Dr. Schaarschmidt says: "The first direct observation was made in 1854 by Hartig, and not by Sachs, as Walter Gardiner states." This refers to the opening passage of my paper in the *Arbeiten des Botanischen Instituts in Würzburg*, Band III., Heft I., where I say: "A most important addition was made to our knowledge of the histology of tissues in 1863 by Sachs, and in the following year by Hanstein, when they demonstrated that in the sieve-tubes first described by Hartig there are perforations in the transverse walls, &c." I made that statement, relying, as I still do, on the authority of Prof. Sachs's text-book (English edition, 1882, p. 89), since it seemed to me that Hartig's observation, which could not be confirmed by "Mohl and others," was actually proved and demonstrated beyond doubt by Sachs and Hanstein, and, moreover, in fresh and not in macerated tissue.

With respect to the main subject under immediate consideration, I shall first make one or two general statements as to the continuity of the protoplasm in plant tissues. In my paper in the *Würzburg Arbeiten*, to which I have already referred, I have spoken of two appearances of continuity: one which I speak of as direct, and the other as indirect. By direct or unbroken continuity, I mean the appearance of a thick protoplasmic process, extending between, and uniting the protoplasmic contents of two contiguous cells: the pits forming one continuous canal, and being uninterrupted by a pit-closing membrane. In this case, therefore, the idea of open pits is necessitated. By indirect continuity I mean the existence of a pit-closing membrane between the two opposite protoplasmic processes in the pits: the membrane being perforated in a sieve-like manner, and thus allowing the two protoplasmic processes to become united to one another by means of delicate protoplasmic filaments which traverse the pit-closing membrane. I further stated that my observations led me to believe that a pit-closing membrane was present in all cases, and that the appearance of a direct unbroken continuity is fallacious. (See also *Roy. Soc. Proc.*, December 13th, 1883.)

Turning now to the consideration of the observations made upon the Florideae, I shall have to differ somewhat with Dr. Schaarschmidt; but, while I do so, I wish it to be quite clearly understood that I do not in the least undervalue the work of those investigators to whom I refer, and who, according to my view, have not actually demonstrated a continuity of the protoplasm from cell to cell, but have only observed facts which render the existence of such a continuity extremely probable. Thus, since I regard the perforation of the pit-closing membrane as proving continuity, I hold that the observations of Bornet, Perceval Wright, and Agardh (I have unfortunately not seen Kolderup-Rosenvinge's paper) have not demonstrated continuity, but have demonstrated that the pit-protoplasm clings with remarkable tenacity to the pit-closing membrane. Hick has simply repeated the observations of these investigators, and of his results the same may be said. Since, therefore, Schmitz (1883) has found that a pit-closing membrane does exist; that it is perforated in a sieve-like manner, and that therefore the continuity is not direct, but indirect, it seems to me that to him alone belongs the credit of having demonstrated the continuity of the protoplasm in the Florideae, and I have myself (*Proc. Camb. Phil. Soc.*, February 11th, 1884) been able to confirm his results as to the existence of the closing membrane in question.

In considering the history of the subject, and leaving sieve-tubes out of the question, it is clear that Tangl's observation (1880) on the endosperm cells of *Phaseolus* and *Strychnos* was the first new discovery in the direction of the continuity of the protoplasm between neighbouring cells. Then came Strasburger's classic work on the cell-wall ("Bau und Wachsthum der Zellhäute," 1882); his observations on the porosity of the pit-closing membranes, and his valuable suggestions as to the probability of cell-wall perforation, together with the citation of instances which already occurred, and his extremely interesting observation with regard to the swarm-spores of *Vaucheria*. Naturally *Volvox*, *Pandorina*, and the zoospores of *Haematococcus* offer other examples of the perforation of the cell-membrane by protoplasm.

After Strasburger came Russow. Russow read his first paper at the January meeting of the Dorpat Society (*Sitzber. d. Dorpater Nat. Gesell.*, 1882), but it did not come into my hands until some time after I had published my first observation (*Quart. Jour. Mic. Sci.*, October, 1882), so that, at least from that point of view, my work was quite independent and original. As to the order of the other papers, I agree with Dr. Schaarschmidt, except that I would like to add to his list the papers of Pfurscheller (*Selbstverlag des k. k. Franz Joseph Gymnasiums*, 1883), Will, (*Bot. Zeit.*, 52, 1884), Tangl (*Sitzb. der k. Akad. der Wiss.*, Bd. 90, 1884), and Goroschankin (*Bot. Zeit.*, 41, 1883).

As to Dr. Schaarschmidt's claiming, in 1884, the suggestion of the universality of the occurrence of continuity of the protoplasm in plant-cells, I think that, considering the state of the subject at that time (April, 1883) something may also be said in my favour, for I find in my Royal Society paper [*Phil. Trans. Roy. Soc.*, April, 1883) the following statement:—"Although I am aware of the danger of rushing to conclusions, I cannot but remark that when these results (which were foreshadowed by Sachs and Hanstein, when they discovered the perforation of the sieve-plate) are taken in connection with those of Russow, it appears extremely probable that not only in the parenchymatous cells of pulvini, in phloem parenchyma, in endosperm cells, and in prosenchymatous bast fibres, is continuity established from cell to cell, but that the phenomenon is one of much wider, if not of universal, occurrence."[1]

Passing on to the results of Dr. Schaarschmidt's second paper, to which he refers, where he gives a very long list of tissues in which he has demonstrated the existence of a continuity of the protoplasm, I should only wish to remark that while he appears to have observed in a satisfactory manner, and with comparative ease, cases that have appeared to me to be excessively difficult, yet his figures of such continuity are not satisfactory, and in many of them it is the direct and not the indirect continuity which his drawings represent. As I have stated elsewhere (*Arb. d. Bot. Inst. Würzburg*) an examination of fresh unswollen tissue with iodine and chlor.-zinc.-iod. will always demonstrate the presence of a pit-closing membrane.

I now come to a subject which I approach with some regret, since, in dealing with it, I have to dissent from the expressed opinions of a number of competent observers, and especially do I feel this regret with regard to one of those papers—viz. that by one of the most distinguished

[1] Mr. Dyer has already very kindly alluded to the subject on my behalf. It will be observed from the text that at that time (April, 1883), owing to the hurry of publication I had not referred to Hartig's paper (February 21, 1863)

ors of plant histology: Prof. Russow. The that of the existence of intercellular protoplasm. naarschmidt has already given the literature. The observation with which I am acquainted is that Frommann ("Zur Lehre von der Bildung der von Pflanzenzellen"—separate pamphlet) who the intercellular spaces of the young stem of *ominunis*, protoplasm; starch grains, and chloro- ins.

bservations as to the existence of intercellular m depend chiefly upon the staining reactions of id sulphuric acid or chlor. zinc. iod. The cell blue, or remains yellow as the case may be: the m, and in certain cases a substance; in or lining cellular spaces, stains dark brown. Or again in ances—*e.g.*, the rhizome of *Aspidium filix mas*— ance in the intercellular space remains uncoloured. bservers have employed other staining reagents lling with sulphuric acid and chlor. zinc iod.—*e.g.*, , eosin, or aniliu blue—and in this case a colour- bserved of the protoplasm on the one hand and tercellular space substance on the other.

g first with the iodine and sulphuric acid or chlor. method, it is obvious that, besides the protoplasm sumes the well-known dark brown colouration, fied, cuticularised or suberised membranes would the same way, and in the case of one of Berthold's *Deut. Bot. Gesell.*) examples, *e.g.*, young stem of *m vulgare*, the substance which so markedly oes actually consist of the external membrane of cellular space, which towards the free surface has ne changes associated with partial lignification *Proc. Camb. Phil. Soc.*, Nov. 10th, 1884), as readily proved by treating a section with aniline and hydrochloric acid, when the well-known gold eaction of lignified tissue appears. In the same substance which does not stain with iodine and c acid might be of a mucilaginous nature, and mucilage of the external portions of the wall of of *Ceratonia siliqua* give the same reaction, viz., uncoloured. But there are cases which are not so deal with, as I have stated elsewhere (*Proc. Phil. Soc.*, Feb 11th, 1884), I found that the n's blue which I had so successfully employed for trating the existence of protoplasmic filaments in dosing-membrane stained not only protoplasm but tain forms of mucilage. Like Russow (*Sitzber. d. Naturfor.*, Sept., 1883), I thought at first that *ba Japonica* I had discovered the existence of ular protoplasm, but I observed later on that this substance could be seen to arise as drops on the walls and that these drops went blue with iodine: monstrating that they were not protoplasm but e. I therefore made experiments with the methy- e which I had found (*Phil. Trans.*, part iii., 1883) o useful as a stain for the cell wall, and so iating in its action. [A solution is made in water ng a trace of alcohol; the solution being diluted ter before use. The section freed from alcohol by washing, is left to stain for about 20 seconds, and mounted in water]. I further found that ne blue stains equally well, all substances formed degeneration of cellulose walls, such as mucilage like. So while Hofmann's blue stains protoplasm cilage, but not cell wall, methylene blue stains cell- l mucilage but not protoplasm. Thus the cell-wall plasm may be readily discriminated in a very ory manner, and without this reaction it would be hard to distinguish the two. Many dyes behave fmann's blue so far as the staining of the mucilage rned, and I have little doubt but that eosin re- it in this respect, though not such a good ining stain for the protoplasm. In the course of xperiments, which I have repeated several times, I have never found intercellular protoplasm but often intercellular mucilage. In all cortex tissues which are often remarkable for their mucilaginous character —*e.g.*, *Viscum*, *Fraxinus*, *Ilex*—mucilaginous degeneration of the free cell-walls very usually occurs, which often—*e.g.*, *Ilex*, *Viscum*—extends even to the whole middle lamella. In *Aspidium filix-mas*, *Blechnum Brasiliense* and other ferns, theso-called cuticularised threads (cuticularfäden) are in reality rods consisting mainly of mucilage which arise as drops on the free surface of the cell-wall and increase in length by repeated basipetal formation. I do not therefore find myself able to allow of the existence of intercellular protoplasm.

As to the middle lamella being protoplasm I can only refer to the statements I made with regard to Frommann and Elsberg's researches (*Quart. Jour. Mic. Sci.*, March, 1883) and I share fully in the opinion of Prof. Russow ("Ueber die Auskleidung der Intercellularen," *Sitzber. d. Dorpat. Naturfor.*, August, 1884) that if such were the case it is clear that we could have no such thing as a mass of tissue resisting great stress. The cells cannot be connected together by protoplasm. As to the existence of the intercellular chlorophyll grains of which Dr. Schaarschmidt speaks, and the chlorophyll grains and starch grains observed by Prof. Frommann, I also share Prof. Russow's view (*loc. cit.*) that the above investigators must have been deceived by some abnormal appearance, for what could be the physiological significance of such a phenomenon? The full details of my researches on the subject will, I hope, shortly appear in the *Quarterly Journal of Microscopical Science*.

WALTER GARDINER

Botanical Laboratory, Cambridge, February 10

THE BANGOR LABORATORIES

THE following is a description of the Laboratories of University College, Bangor, which were opened by Sir William Thomson on the 2nd inst. The illustration shows the ground floor arrangement; in the upper floor are a magnetism-room and an optical gallery.

The new physical and chemical laboratories occupy the site of the old stables and coach-houses of the "Penrhyn Arms Hotel," which is now used as the main building of the College; and, to lessen expense, a plan has been adopted by which the old walls are, as far as possible, taken advantage of for outside walls and partitions. To utilise the available space to the utmost it was decided to roof in the whole area, which measures about 120 feet by 80 feet. This area is bounded on the east by the main building of the College; on the south by a private road which runs nearly parallel to the Shrewsbury and Holyhead turnpike road, and gradually ascends until opposite the laboratories, the ground is about 20 feet above the level of the turnpike; on the west and north by the private grounds of the College.

At the extreme east end of the south front of the laboratory buildings is a wide door opening into a vestibule, from which a passage leads north, and terminates in a wider space or hall. From this hall a long corridor runs parallel to the south front, dividing the floor space into two nearly equal parts. Of these the southern is set apart for physics, the northern for chemistry.

The physical and chemical lecture-theatres (23,41) are of the same size, 32 feet square and 19 feet high, and are placed side by side with the corridor as a separating space between them. The internal arrangements are nearly the same in both rooms. The students' entrances are opposite one another in the corridor. The benches, eight in number, rise from the front to the back of the room, and front toward the west. The lecture-tables are placed about 4 feet from the front bench, and between each table and the west wall there is a clear space between 7 and 8 feet wide. In the physical lecture-theatre the table is supported on four pillars of masonry, and is en-

tirely independent of the floor of the room. The tables differ somewhat in their arrangements, one being designed specially for chemical, the other for physical, work. Both have been fitted with the most recent improvements, and some novel appliances.

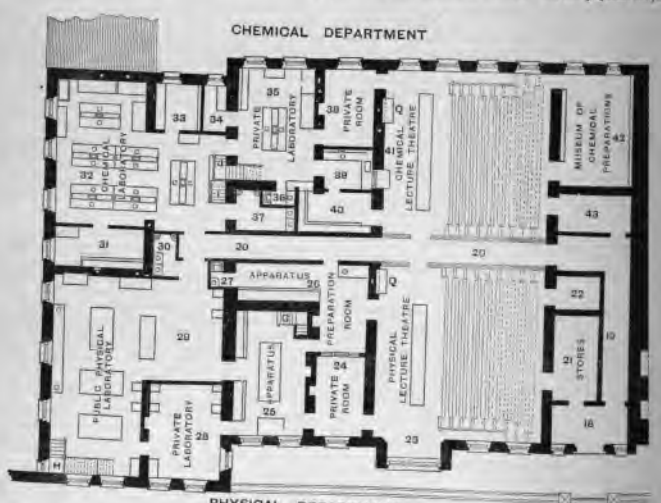
At the south end of the physical lecture-theatre, opposite the end of the lecture-table, is a large window filled with plate glass, and projecting so as to give additional space within the room for experimental work. A stand for a heliostat is fixed outside, and a table for optical instruments will be placed in front of the window inside.

An open space, extending to the ridge, and about 12 feet square, has been left above the centre of the physical lecture-table, and in this way a clear height of about 30 feet has been obtained for long pendulums, vibrating cords, &c. A gallery surrounds this space near the top to allow the beams, from which such appliances are suspended, to be easily reached.

By means of blinds, working on spring rollers controlled by cords from one place near the table, the windows of each lecture-theatre can be completely darkened in an instant.

A passage leads from each lecture-theatre to the space beneath the benches, which has been utilised for storage, and gives access to two rooms behind. In the physical department these are diagram-room and store-room (21, 22); in the chemical department store-room and class museum (43, 42), respectively.

To each department the space intervening between the lecture-theatre and the public laboratory is occupied with the professor's private room and laboratory, and the preparation and apparatus rooms. On the physical side, immediately to the west of the lecture-theatre, are the private room and preparation room (24, 26), which communicate directly with the lecture-theatre. Beyond the private room is the apparatus room (25), which overlaps the preparation room, and communicates directly with it. The preparation room is L-shaped, one limb of the L running back along the north wall of the apparatus room. This part of the room is open to the roof, to allow the room to be lighted by a window at the west end, placed above the level of the western part of the building, and by a large skylight, and is fitted along one side with cases as a supplementary apparatus room. An available height of about 25 feet is obtained in front of these cases, and is designed for elasticity experiments. A gallery over the window allows the roof above this part of the room to be reached by means of a ladder. The limb of the L immediately behind the lecture room is fitted with a work-table and provided with a fireplace, as a preparation room for the lecture experiments.



The New Laboratories of University College, Bangor.

To the west of the apparatus room is the private laboratory (28), about 20 feet by 18 feet, communicating with the preparation room and private room on one side, and with the public laboratory (29) on the other. In the south-west corner of this room a slate balance table has been built into the wall, and near the other end of the room slate tables have been fixed to the wall for galvanometers and electrometers. A single work-table, fitted with gas, occupies the centre of the room, and a smaller work-table with gas and water the south-east corner.

The general physical laboratory (29) is a large room over 1000 feet square in area, running along the west end of the space allotted to the physical department. The

tudent's entrance is from the corridor, and adjoining this ntrance is a lavatory and cloak-room (30) for their use. The laboratory is fitted with work-tables for about twenty tudents. Along the west wall is a long work-table, fitted vith gas and water. The space below this table is divided nto cupboards and drawers for the use of students. On he north wall a draught chamber, and combined heating tore and sand bath, of novel design, have been provided, nd at different positions slate slabs for galvanometers, ;c., have been fixed to the walls as in the private labora- ory. The roof is left open to add to the height of the oom, and for convenience for experimental arrangements. The room is lighted by windows in two sides, and by a ow of large skylights on each side of the ridge.

A staircase, G, leads from the apparatus room to two rooms n the second floor. One of these has been constructed vithout iron to ensure a uniform magnetic field. No nagnets or a large mass of iron will be stored below, and he room will be available for absolute electric measure- nents. The other room is a gallery about 37 feet long nd 10 feet wide, constructed for optical and photometric vork.

A second stairway leads to a small room communicating vith the gallery above the lecture table, and with a flat space on the roof which has been constructed as a station or observations of atmospheric electricity. The collector of electricity will be placed outside on the flat roof, nd connected with a station electrometer in the small oom below.

A stair, H, at the south end of the general physical labora- ory leads to some valuable rooms in the basement, which ave been set apart for practical electricity, workshop with lathe and forge), magnetic room, battery room, store oom, &c.

Returning to the chemical side, the preparation and pparatus rooms (39, 40) occupy the position corresponding o that of the preparation and elasticity rooms on the hysical side. The preparation room is fitted with proper work-tables, and communicates with the lecture-theatre by a sliding panel. The private laboratory (35) corresponds to the apparatus room of the physical department. It is fitted with a work-table for four persons, and a large draught chamber and sand bath, and communicates with a special balance room (34) on the west side. The general chemical laboratory (32) corresponds in position with the physical laboratory, and is fitted with work-tables for twenty-four students. These tables have been constructed according to a special design embracing all the most recent improvements. Around the north end of the labora- tory have been placed sand baths, draught chamber, large distilling table, sink and table for water and air baths. A portion of the south end of the laboratory has been partitioned off and fitted up as a combustion and blow- pipe room (31). At the north end a balance room (33) has been fitted up, and in this room, as well as in the private balance room, the floor is completely isolated from the laboratories, and the tables for the balances are supported on strong brackets firmly fixed to the stone walls. The lighting of the laboratory is managed in the same way as that of the physical laboratory, the skylights along the east side of the ridge of the roof being made to open.

A staircase, J, leads from the general laboratory to the first floor of the chemical department, which is occupied with rooms specially designed and fitted for photographic, gas analysis, and spectroscopic work respectively. A ladder leads to a flat roof for experiments which require to be made in the open air. A second stair, I, leads from the general laboratory to the basement, where there is a rough operation room, joiners' shop, and metallurgical room.

The arrangement of the rooms and the construction of the lecture tables, work-tables, and other fittings have been carried out by Mr. Richard Davies, architect, Bangor, under the direction and superintendence of Profs. A. Gray (Physics) and J. J. Dobbie (Chemistry), and in accordance with sketch plans furnished by them.

The addresses on Scientific Laboratories which Sir William Thomson delivered on the opening of the above laboratories we shall give in our next number.

NOTES

THE Geological Society has this year awarded the Wollaston Medal to Mr. George Busk for his researches on Fossil Polyzoa and on Pleistocene mammalia; the Murchison Medal to Prof. Ferdinand Roemer, the eminent palæontologist of Breslau; the Lyell Medal to Prof. H. G. Seeley, for his long-continued work on Fossil Saurians; and the Bigsby Medal to M. Renard, of the Brussels Museum, on account of his petrographical researches.

THE annual meeting of the Paris Academy of Sciences was held on February 23 before a very large audience. M. Rolland, the President for 1884, was as usual in the chair. He delivered the customary address, alluding to the members of the Academy who died during the past year, and gave a *résumé* of the principal scientific facts of the same period. M. Arago (Emmanuel), the eldest son of François Arago, who is French Ambassador to Berne, had come to Paris in order to be present at the delivery of the *éloge* on his illustrious father, who died thirty years ago. The delay must be attributed to the political career of the Perpetual Secretary of the Academy of Sciences, who, having been a member of the Government of the second French Republic, was not a *grata persona* to the then authorities. The speech was delivered by M. Jamin, who was one of his successors in the seat he occupied in the section of Physics. M. Bertrand fills his place as Perpetual Secretary. The number of prizes delivered is too great to be reported at full length. We must content ourselves by mentioning the laureates who have worked at questions of general interest. A part of the prize of 6000 francs for progress in efficiency of naval forces has been awarded to the Hydrographic Mission to Tunisia, and to a work of M. Baills on artillery. The Monthyon prize has been awarded to M. Riggenbach, a Swiss engineer, for his railways in mountainous districts. The Poncelet prize, for progress in mathematics, to M. Houel, for the whole of his works. The Lalande prize, for astronomy, to M. Radau, for a memoir on refractions; and the Salz prize, for the same science, to M. Gurzel, for a disquisition on ancient eclipses in order to determine the value of the secular acceleration of the motion of the moon. The Tremont prize has been awarded to M. [illegible] Taste for his works on meteorology. M. Marsault has received a gratification of 1500 francs for his studies on lamps for miners. This gentleman is director of the Bessages collie[illegible] The cholera prize was not awarded. M. Durand-Claye, engineer of the Municipal Service of Paris, who is a strong supporter of the system called "*tout à l'égout*," took a prize for statistics for his researches on diffusion of typhoid fever.

MR. ALEXANDER AGASSIZ has resigned his position as Fellow of Harvard College, and *Science* states that his resignation was naturally accepted by the Corporation with great reluctance. The *Bulletin* of the University just published contains the formal notes taken at the meeting of October 24, and state "that the wide range of his sympathies and interests, the confidence and affection which he inspired, and the variety of information which he possessed both as a man of business and as a man of science, made his services as a fellow of singular value to the University; that his great gifts within the past thirteen years to the scientific departments, and especially to the Museum of Comparative Zoology, which amount to more than half a million of dollars, make him one of the chief benefactors of the University, and entitle him to its profound gratitude."

THE death is announced, at Cannes, of Mr. John Francis Campbell of Islay, at the age of sixty-four years. Mr. Campbell did work in various departments of science. Many years ago he collected the folk-lore of the Western Highlands, and published a large selection of his collections. Mr. Campbell was also a geologist, and in his "Circular Notes" and "Frost and Fire" will be found many geological notes as well as speculations. Quite recently, also, he published a curious book on "Thermography," and he was the inventor, our readers will remember, of the sunshine-recorder at Kew.

WE regret to learn of the death of Mr. Thomas C. Archer, Curator of the Museum of Science and Art, Edinburgh.

M. POYDESSAU, the French engineer who assisted Lieut. Bonaparte Wyse from 1876 to 1878 in his surveys of the Isthmus of Panama, in view of a canal to connect the Atlantic and Pacific, died at Panama on January 7.

Die Natur announces the death of Dr. Friedrich Ritter von Stein, Professor of Zoology in the University of Prague, who is known by a work on Infusoria; and of General Sonklar, one of the first and oldest of Austrian Alpine climbers, whose orographic work in connection with the Austrian Alps has gained him much credit in his native country. He was Professor of Geography at the Military School of Vienna; his latest work was a chart of the rainfall of the Austro-Hungarian Monarchy.

WE learn also of the death of M. Louis Godard, the aëronaut. In 1863 he and his brother Jules went up with Nadar, who still lives, in the monster balloon called *Le Géant*. A breakage in the mechanism necessitated a speedy descent, during which a gust of wind turned the car upside down. The thirteen passengers had barely time to cling to the ropes, and, the grappling irons breaking, the car dragged half a mile on the ground before a landing could be effected. During the siege of Paris Godard left by balloon, and at Tours served on an aëronautic commission. He took no part in recent experiments and discussions on navigable balloons.

ON the afternoon of January 19, we learn from *Science*, the first balloon ascent ever made in the United States solely in the interest of meteorology took place at Philadelphia. Gen. Hazen, chief Signal Officer, U.S.A., recognising the importance and value of a more complete knowledge of the upper atmosphere, entered into a contract some time ago with the well-known aëronaut, Mr. S. A. King, for a number of "trips to the clouds," an ascent to be made at any time on eight hours' notice. The U.S. Signal Service has had this subject under consideration for several years. Prof. Abbe began in 1871 to collect meteorological records made in balloons. In 1872 the records of fifty ascents had been tabulated, studied, and valuable results obtained. In 1876 1000 small balloons were sent with the *Polaris* expedition, to be used in determining the height of the clouds; but, owing to an unfortunate accident, they could not be utilised. At various times the chief Signal Officer has sent observers on balloon excursions which were made for purposes other than scientific. The considerable certainty with which the movement of a storm can now be predicted renders it possible and desirable to make systematic use of the balloon in the study of unusual atmospheric conditions, and the series of ascents just begun is planned with that end in view. Among other things it is desired to determine the difference in the temperature gradient in well-defined "high" and well-defined "low" pressures. For this purpose it is necessary to foretell the arrival of a particular atmospheric condition at Philadelphia, from which place the ascents will be made. This can readily be done so as to give the aëronaut eight hours' notice for the preparation of his balloon, and the observers who accompany him sufficient to reach Philadelphia from Washington. The first ascent expected to be rather experimental and suggestive in its character. It was the intention to start at 7 A.M. on 19th, and a telegram to that effect was sent to Mr. K[ing] responded that he would be ready. But, owing to the cold, it was found that the balloon could not be handled ing without danger of cracking; and waiting for the sun it up caused so much delay, that the start was not made p.m. The balloon was the *Eagle Eyrie*, holding 25,000 feet when filled, and having a lifting power of [about] pounds. The occupants of the car were Mr. King and Hammond, a skilful observer detailed from the office Chief Signal Officer for the purpose. Mr. Hammond ried with him a complete outfit for making barometric metric, and hygrometric observations. Owing to hour of starting, the observations made were not so as could be desired, although seven complete sets were before darkness rendered further reading impossible and quiet landing was effected at about 7.30 P.M. near of Manahawken, on the New Jersey coast. The grea reached was somewhat over one mile. This trial-tri gested some modifications in the plans, which will ren ascents more successful. The danger incident to ascent is greatly over-estimated by many. In the c an experienced and skilful aëronaut the risk to life is hardly greater than on a railway train or a Volunteers for this service are by no means wanting those connected with the signal service; and Prof. A desirous of knowing what is going on "inside of a b he means to make an ascent himself in order to find

THE Faculty of Harvard College, by a majority of two, have decided that Freshmen may be admitted matriculating in Greek. It is expected that the Classics suffer a further comparative decline, the literature an the United States being given greater prominence curriculum.

AT a meeting of Convocation of the London Univers on Tuesday, Lord Justice Fry moved, "That, in the Convocation, the objects of the Association for pro Teaching University for London would, if carried int this University, add to its usefulness and importance Lordship said that, while he did not wish to cast the slur on the past history of the University, he maintain there should be a combination of teaching with exam In his opinion the success of the scheme was inevitable would be far better that it should be carried out by versity than by another examining body. The motion been carried, the Special Committee was authorised effect to the resolutions passed.

THE December number of Prof. Caporali's *Musa* which completes the first year of this remarkable pe continues to advocate his peculiar system of the univ unabated vigour and learning. His theory of psychogo here advanced a further stage, and it is now contended that psychis is co-eternal with matter, but that it is the rising-point of all evolution. In the present issue the chief are: "Modern Italian Thought," "The Pythagoric Cosmic Evolution," and "The Anglo-Saxon Anticleric lution." Notwithstanding some curious misconceptions mentioned paper will be read with interest by English of contemporary thought.

AN extensive Fish Culture Establishment is in course struction at Delaford Park, Iver, Buckinghamshire, in con with the National Fish Culture Association. The site a pl close to the River Colne, which is famous for its trout affords an abundant supply of fresh water for the required. A number of ponds are being formed approved scientific principles, in which the *Salmonidæ*, coarse fishes, &c., will be [propa

nity at large. The cultivation of the German carp ive considerable attention, this fish being far superior h species both as regards its edible qualities and rapid growth.

ew to effectually prosecuting marine fish culture on he principles, the National Fish Culture Associa- ler consideration a scheme for carrying out a series ns on the temperature of the sea at various stages, btain a more thorough and concise knowledge of bits, food, &c. Thermometers for this purpose are manufacture, and will be distributed to those selected under certain rules and regulations. The Duke of greatly interested in the subject, and has promised ion in furthering the movement, which he considers rtant one.

nsignments of eggs of the *S. irvenensis* and white fish been received at the South Kensington Aquarium m. Prof. Baird, Commissioner of Fish and Fisheries ed States. All the eggs are in a healthy condition point of incubation. There have been about a dozen irths amongst them, but, of course, the young fry so e live. Prof. Baird has intimated his intention of a further instalment to South Kensington shortly.

VOEIKOFF writes with reference to a note in NATURE 29 (p. 296), in which it is stated that the Russian are preparing an expedition to Western Siberia to sulphur deposits mentioned by MM. Kalitin and These deposits, he states, are not in Western Siberia, o-called old beds east of the Caspian, in a region used to call Central Asia. It is not exact also to deposits of Tchirhat (*not* Tchirkoto) in Daghestan nes till now known in Russia. Sulphur deposits n some places near the Volga, and are due to the on of the gypsum so often met with in the Permian Two of these have been worked, one in the century, that of Serwaja Gora, on the right bank of somewhat above Samara, and another quite recently, rewa, about 20 versts above the town of Tetjuchi, of Kazan.

A recent meeting at Annisquam, on the coast of tts, Mr. J. S. Kingsley described the foundation and e Annisquam Marine Laboratory. Prof. Hyatt, of been in the habit of inviting some of his students to him to this place during the summer to study the a so abundant there. From the number of applica- ssured that there was a demand for a marine laboratory near Boston which should be practically free to all. n's Educational Society of Boston became interested ect, and advanced the money necessary to fit it up. the charge of the Boston Society of Natural History, it opened for students in June, 1881. The object of ory, which appears to be upon only during the summer n the colleges, is to furnish students with an oppor- plying marine animals and plants in the best possible ome of those who enter are competent to conduct vestigations, and they are left to follow out any line choose. The majority, however, attend to get a and to fit themselves for teaching. Mr. Kingsley m aim of the laboratory to be to teach the structure pment of animals, and the methods of study best produce teachers and investigators. Each student, ently qualified, dissects a series of types of the larger m as the anemones, starfish, clams, lobsters, squid, &c. ains a drill in the methods of investigating the em- of marine forms. The numbers of students range ine and twenty-one. The laboratory is under the immediate charge of Mr. B. H. Van Vleck. A windmill has lately been added to pump salt water into the building, thus supplying a tank on each of the tables, besides three large aquaria in the centre of the room. The object was to keep the specimens studied alive in confinement—a task of no small difficulty.

AT a meeting held at Edinburgh on Monday it was resolved to hold an international exhibition in that city in the summer of 1886 of industry, science, and art. A committee was appointed to carry out the details.

THE Prince of Wales, as President of the International Inventions Exhibition, has delegated to a Commission selected from among the members of the Executive Council the duty of making arrangements for the effective carrying out of the work of the International Juries. This Commission consists of Sir Frederick Abel (Chairman), Sir F. Cunliffe-Owen, Sir George Grove, Sir E. J. Reed, M.P., Mr. John Robinson, Mr. R. E. Webster, Q.C., with Mr. Trueman Wood (Secretary of the Society of Arts), Secretary of the Commission. His Royal Highness has expressed his wish that, as was the case in the International Health Exhibition last year, the exhibitors should themselves aid in the selection of jurors by submitting the names of those gentlemen whom they may consider most eligible. Exhibitors will, therefore, be asked to send in on a form, to be provided for the purpose, names of gentlemen who might be invited to serve as jurors. The actual selection of jurors will rest with the Jury Commission, who will endeavour to give full weight to the opinions expressed by exhibitors, but will not be restricted to the list of names suggested.

THE Tenth Report of the Boulder Committee of the Royal Society of Edinburgh has come to hand. It is the final report of the Committee appointed in 1871 to collect information regarding erratic blocks or boulders in Scotland, and the Committee do not expect that, by continuing inquiries on the lines available to them, much additional information of importance would be obtained. At all events they regard it as desirable now to arrange their information obtained during the past fourteen years in such a way as to make it more readily accessible. Accordingly they append an abstract of the information in the previous nine reports, so that the present volume may be regarded as a complete record of the work of the Committee. There is also added a "summary of facts, and of inferences apparently deducible from these facts, bearing on the question by what agency boulders were transported to their present sites." The suggested agency is that "of an oceanic current from some north-westerly quarter, bringing masses of floating ice, with boulders upon them, which boulders were deposited on our hills (then submarine) when the ice stranded on these hills." With regard to the question from what country these boulders could have come, and what could have produced the current, the Committee think that though answers might be suggested, they would be going beyond the objects of their appointment in doing so. Their proper province, they say, has been "simply to collect facts bearing on boulders in Scotland, embracing their distribution, their positions, and the agencies probably concerned in their transport. To explain the source or origin of their agencies, or, in other words, to unravel the conditions of the earth's previous history, so as to account for these agencies, is a problem the solution of which must be left to others."

A FULL Report on the East Anglian earthquake of April 22 last, which was probably the most destructive event of its kind in England within the historic period, will be read at the monthly meeting of the Essex Field Club on Saturday next. The Report has been very carefully prepared for the Council by Mr. R. Meldola, with the assistance of many members of the Club and

others. A collection of photographs showing the structural damage will be exhibited. The attendance of those interested in the subjected is invited.

THE last earthquakes in Southern Spain (February 15) were incident with slight subterranean motions in Algiers and in Savoy. The valley of Isère and Chambery principally felt them.

AN exceptionally severe shock of earthquake was felt at Geraldton in Western Australia on January 5. It was preceded by a subterranean rumbling lasting ten seconds. Houses were violently shaken, and the walls rocked, causing much consternation. The sea subsided three feet in a quarter of an hour, returning gradually to its ordinary level. The weather at the time was clear and the temperature cold.

MESSRS. SONNENSCHEIN AND CO. have published a third edition of Dr. Coppinger's "Cruise of the *Alert*."

WE have received from the Royal Museum of Anthropology of Leyden No. 1 of its "Anthropological Notices," by Drs. Serrurier and Jenkate. It deals with the Kroomen of Liberia, arranges the observations in them after the Broca-Topinard method. Only two individuals of the tribe, who had arrived as sailors on board a vessel at Rotterdam, were examined. They came from the region situated between Monrovia and the River Sesters. A plate containing an outline of the feet of each, and of the hand of one, is also added.

THE writer of the letter on "Human Hibernation" in NATURE of February 5 (p. 316) was Col. C. K. Bushe.

THE additions to the Zoological Society's Gardens during the past week include a Serval (*Felis serval* ♂), a Civet Cat (*Viverra civetta* ♀) from West Africa, presented by Mr. T. J. Alldridge, F.Z.S.; a Common Badger (*Meles taxus* ♀), British, presented by Mr. Cuthbert Johnson; two Common Foxes (*Canis vulpes* ♂ ♂), British, presented by Lady Brassey, F.Z.S.; two Pileated Jays (*Cyanocorax pileatus*) from Buenos Ayres, presented by Mr. Theo. Walsh; a Roseate Cockatoo (*Cacatua roseicapilla*) from Australia, deposited; two Malayan Squirrels (*Sciurus nigrovittatus*) from Malacca, a Four-horned Antelope (*Tetraceros quadricornis* ♀) from India, a Golden-winged Woodpecker (*Colaptes auratus*) from North America, a Pine Grosbeak (*Pinicola enucleator*), European, a Brazilian Teal (*Querquedula brasiliensis* ♀) from Brazil, purchased; four Long-fronted Gerbilles (*Gerbillus longifrons*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

THE DOUBLE-STAR PIAZZI XIV. 212.—Piazzi first remarked from his own observations between 1800 and 1809, the large proper motion of this star, which was determined by Argelander in vol. vii. of the Bonn Observations to be 2″·015 annually, in the direction 151°·2. "Der Begleiter 8·4m.," he adds, "theilt die Bewegung des Hauptsterns; beide bilden also ein System, dass eine ziemlich rasche Aenderung der Distanz und des Positionswinkels zeigt. . . ." The following measures suffice to show the nature of the change in the relative position of the components:—

Herschel and South	1823·3	...	270°·2	... 10″·82
Burnham	1881·4	...	291°·3	... 15″·38

The most reliable measures may be closely represented by the formulæ—

$$D \sin P = -12''.502 - [8.78020] \cdot (t - 1850{\cdot}0)$$
$$D \cos P = +\ 2''.613 + [8.96275] \cdot (t - 1850{\cdot}0)$$

But there is one point of interest connected with this star to which attention seems hardly to have been directed—viz. the strange discordances in the estimates of the magnitudes of the components. To illustrate this we may quote the following from a much larger number of estimates recorded:—

At 6h. Greenwich Mean Time

		Star A		Star B
Herschel... ...	1835·45	...	3½	...
,, ...	1837·46	...	7	... 7
Jacob	1856·24	...	6	... 9
Argelander ...	1862·89	...	6	... 7½
O. Stone ...	1877·37	...	4·9	... 8·4
Flammarion ...	1877·37	...	7·0	... 8·5
O. Stone ...	1877·51	...	5·5	... 8·7
Burnham ...	1879·47	...	5·0	... 8·1
O. Stone ...	1880·32	...	6·0	... 8·9
Burnham ...	1881·36	...	8·0	... 8·1
		...	6·5	... 8·0

Gould has 6·3 and 7½. The star is not in Argelander's [illegible] *metris*, nor has Heis got it. Argelander made a difference of 3½ magnitudes in 1862–63, Flammarion in 1877 rated the star only one magnitude below the other. The difference between Burnham and O. Stone at nearly the same time in 1881 may have been due to atmospheric conditions at Cincinnati, but the star appears to be worth watching for variability; compare Argelander in 1862 with Burnham in 1881 or with Gould.

WOLF'S COMET.—The following ephemeris for 6h. G.M.T. is founded upon one for Berlin midnight, calculated from Krueger's last orbit, by Dr. Lamp, of Kiel:—

	R.A. h. m. s.	Decl. ° ′	Log. distance from Earth

GEOGRAPHICAL NOTES

ed that the King of the Belgians is conferring with ie, president of the French Geographical Society, ject of the formation of an International Geographical

issue of the *Izvestia* of the Eastern Siberian branch sian Geographical Society contains an interesting d. Doubrof on his journey to Mongolia. The author, ed by only one man, has explored the upper course of a and reached the hitherto unvisited source of this ary of Lake Baikal. Unhappily, on his return journey evented from following the exploration of its middle whole journey having been undertaken at so small that the author had sharply to calculate every rouble to expend. The want of barometrical observations gh tablelands of the Upper Selenga is especially re- nd it is not wholly compensated by a mere topo- escription. A table of the times of the freezing of ian rivers and of the breaking of the ice is given ime fasciculi, as also several notes on the Lena ical station—already old—and on the Yakutsk

le in children within the province of Yakutsk is the an interesting note in the same journal. The ographical Society had received a note from one of s, who thus depicted the lot of girls within the pro- he last century the poorest Yakute who had no means ing a large family, took his new-born child in a f birch-bark and hung it on a tree in the forest to die r. But the richer Russian merchants began to buy m their poorer Yakute clients, and so several Russians whole families of servants. This custom induced the mmunities to take care of the poorest children, and unity was bound to feed them, under the name of children, who spent three days in the houses of the mbers of the community, two days in those of the wealthy, and one day with the poorest. But of late has arisen of selling children, and especially girls, sk merchants, who sell them further to the Yakutes nses of the Olekminsk district. The parents sell irty to forty roubles (3*l.* to 4*l.*), and in Olekmir they for sixty roubles, sometimes eighty roubles. Of trade is made under the cover of "taking children ." The Irkutsk Society having taken interest in this ation, it has received information from Yakutsk , and from a well-known student of Yakute life, hoff. It appears from these communications that really exists, the chief impulse to it being given, less k a purchased girl might do than by the possibility of for her the *kalym*, that is, the money paid by men ing a wife. Woman labour is at so low a price that have a woman in his household and pay her half a ation, "*for a shirt*," per year. But the *kalym* reaches prices. One rich Yakute has recently sold his to a Tungus for 3000 reindeer, and the same price ly given by a half-idiotic Yakute for the daughter of kute. Middendorff quotes also several instances of h *kalym* paid for girls, its average being about 500 When a Russian priest sold a girl whom he had r five sables and ten skins, it was considered as a price. Altogether, the *kalym* is the chief cause of g the trade in girls, together with the gradual ment of the Yakutes.

pan Gazette publishes a brief statement from Mr. chnical adviser to the Imperial Mint at Osaka, on ations during a recent journey through part of Corea. en days at Seoul, the capital, and twenty days on the oute between that place and the port of Fusan. He erve any indication of mineral wealth. There were f mines, and nothing beyond doubtful indications of ins in one or two places. There are no mountains exceeding about 4000 feet in highest elevation, and no characteristic volcanic cones. The central range was crossed by a pass 2300 feet above the sea-level. The forests were of no great extent, but very extensive tracts of cultivated ground, evidently yielding a large surplus production of rice, barley, and beans, were noticeable throughout. There was a marked absence of any manufacturing industry, or of indications that anything beyond food-products receives attention. The traffic on the roads was limited to that between neighbouring districts only, and this was very little. The beasts of burthen employed were rarely horses, frequently bullocks, and chiefly men. There is a total absence of any signs of wealth, and the resources of the country appear to lie solely in agriculture. There is no money, and no prospects of any foreign trade.

THE last number of *Le Mouvement Géographique* has some interesting information about the celebrated first letter from Columbus. All interested in the early history of America know of the different editions of this letter, which was first published in 1493. Bibliographers mention seven of them : (1) one in Rome by Stephen Plannck ; (2) one called the Libri Lennox ; (3) one in Rome by Eucharius Argentens ; (4) a second by Plannck at Rome ; (5) a Paris copy ; (6) a second Paris copy ; (7) one discovered in Turin by Harisse. To these an eighth has just been added by Ruelens, who discovered the only copy of it known to exist in the Royal Library at Brussels. It is a small pamphlet of four leaves in quarto, of thirty-eight lines, without figures or signature, in semi-Gothic characters. It appears to have been purchased between 1815 and 1830 by the Royal Library. Its title is : "Epistola Christophori Colom : cui etas nostra multum debet." The title then goes on as follows : "De Insulis Indie supra Gangem nuper [for rupez] inventis. Ad quas perquirendas octavo ante mense auspiciis et ere invictissimi Ferdinandi Hispaniarum Regis missus fuerat : ad magnificum Dominum Raphaelem Sanxis : ejusdem serenissimi Regis Tesaurarium missa : quam nobilis ac litteratus vir Aliander de Cosco ab Hispano idiomate in latinum convertit : tertio Maii MCCCC. XC. III. Pontificatus Alexandri Sixti Anno prime." Although the little pamphlet does not bear the name of a publisher, M. Ruelens, by comparing the works of the great Flemish printers, has discovered that Martens was the person. This individual distinguished himself among all his fellows about the end of the fifteenth century, at Antwerp, by his intelligent and progressive character. He was a great publisher of his day ; he issued more than fifty writings of Erasmus, More's "Utopia," works of Savonarola, and many others. Facsimiles of the letter have been printed by M. Ruelens, and fifty of them, numbered and paged, are offered for sale. The discovery of this relic of geographical discovery, as well as of early Flemish printing, is an event of great interest.

THE *Echo du Japan* reports the arrival in Japan, at the beginning of the year, of M. Joseph Martin, a French traveller, who has just been exploring the parts of Siberia hitherto very little known. His principal journey was from the Lena to the Amoor, across the Stanowai chain of mountains. During his explorations he was able to make geographical and geological collections, which are intended for the Paris museums. In consequence of hardships endured on the journey, two of his native followers died and one lost his reason.

IN a paper read before the Statistical Society on the 17th inst. Sir Richard Temple endeavoured to check the various official returns of the population of China by applying the results obtained from the population statistics of British India. The various statements made by the Chinese Government as to the numbers of people under its rule show violent fluctuations, those of the last century and a half varying between 436 and 363 millions. These returns, as Prof. Douglas pointed out, varied with the purposes for which the enumerations were made. China proper and India, said Sir Richard Temple, are about the same area—a million and a half of square miles. Both countries are under similar conditions, physical, technical, climatic, geographical. In both there is a strong tendency to multiplication of the race. In both the population loved to congregate in favoured districts, to settle down and multiply there till the land could scarcely sustain the growing multitudes, and to leave the less favoured districts with a scanty though hardy population. The average population of the whole of India is 184 to the square mile, and if this average be applied to China (exclusive of the Central plateau) it gives a population of 282,191,600 souls. The writer then compared, one by one, the eighteen

provinces of China proper with the districts in India corresponding nearly in physical characteristics and cultivable area, and, summarising these computations, he found that, over a total area of 1,500,650 square miles, the population, according to this estimate from the Indian averages, would be 282,161,923, or, say, 283 persons to the square mile, while the latest official returns obtained from China show 349,885,386, or 227 inhabitants to the square mile. The general conclusion, he said, might be that the latest Chinese returns, though probably in excess of the reality, did not seem to be extravagant or incredible on the whole if tested by the known averages of the Indian census.

THE FORMS OF LEAVES[1]

SIR JOHN LUBBOCK said that, gratify as we all appreciated the exquisite loveliness of flowers, we must admit that the beauty of our woods and fields was as much due to the marvellous grace and infinite variety of foliage. How is this inexhaustible richness of forms to be accounted for? Does it result from an innate tendency of the leaves in each species to assume some particular shape? Has it been intentionally designed to delight the eyes of man? Or has it reference to the structure and organisation, the wants and requirements of the plant itself?

Now, if we consider first the size of the leaf, we shall find that it is regulated mainly with reference to the thickness of the stem. This was shown, for instance, by a table giving the leaf area and the diameter of stem of the hornbeam, beech, elm, lime, Spanish chestnut, ash, walnut, and horse-chestnut. When strict proportion is departed from, the difference can generally be accounted for.

The size once determined exercises much influence on the form. For instance, in the beech the leaf has an area of about 3 square inches. The distance between the buds is about 1½ inches, and the leaves lie in the general plane of the branch, which bends slightly at each internode. The basal half of the leaf fits the swell of the twig, while the upper half follows the edge of the leaf above, and the form of the inner edge being thus determined decides that of the outer one also. In the lime the internodes are longer and the leaf consequently broader. In the Spanish chestnut the stem is nearly three times as stout as that of the beech, and consequently can carry a larger leaf surface. But the distances between the buds are often little greater than those in the beech. This determines, then, the width, and, by compelling the leaf to lengthen itself, leads to the peculiar form which it assumes. Moreover, not only do the leaves on a single twig admirably fit one another, but they are also adapted to the ramification of the twigs themselves, and thus avail themselves of the light and air, as we can see by the shade they cast without large interspaces or much overlapping.

In the sycamores, maples, and horse-chestnuts the arrangement is altogether different. The shoots are stiff and upright, with leaves placed at right angles to the plane of the branch, instead of being parallel to it. The leaves are in pairs, and decussate with one another, while the lower ones have long petioles, which bring them almost to the level of the upper pairs, the whole thus forming a beautiful dome.

For leaves arranged as in the beech, the gentle swell at the base is admirably suited; but in a crown of leaves, such as those of the sycamore, space would be thereby wasted, and it is better that they should expand at once, as soon as their stalks have carried them free from the upper and inner leaves. Hence we see how beautifully the whole form of these leaves is adapted to the mode of growth and arrangement, of the buds in the plants themselves.

In the black poplar the arrangement of the leaves is again quite different. The leaf-stalk is flattened, so that the leaves hang vertically. In connection with this it will be observed that, while in most leaves the upper and under surfaces are quite unlike, in the black poplar, on the contrary, they are very similar. The stomata or breathing-holes, moreover, which in the leaves of most trees are confined to the under surface, are in this species nearly equally numerous on both. The "compass" plant of the American prairies, a yellow composite not unlike a small sunflower, is another plant with upright leaves, which, growing in the wide open prairies, tend to point north and south, thus exposing both surfaces equally to the light and heat. It was shown by diagrams that this position also affects the internal structure of the leaf.

In the yew the leaves are inserted close in one another, and are long and linear; while in the box they are further apart and broader. In the Scotch fir the leaves are linear, and 1½ inch long; while in other pines, as, for instance, the Weymouth, the stem is thicker and the leaves longer.

In the plants hitherto mentioned one main consideration appears to be the securing of as much light as possible; but in tropical countries the sun is often too powerful, and the leaves far from courting, avoid the light. The typical acacias have primate leaves, but in most Australian species the true leaves are replaced by a vertically flattened leaf-stalk. It will be found, however, that the seedlings have leaves of the form typical in the genus. Gradually, however, the leaf becomes smaller and smaller, until nothing is left but the flattened leaf-stalk or phyllode. In one species the plant throughout produces both leaves and phyllodes, which give it a very curious and interesting appearance. In eucalyptus, again, the young plant has horizontal leaves, which in older ones are replaced by scimitar-shaped phyllodes. Hence the different appearance of the young and old trees which must have struck every visitor to Algiers or the Riviera.

We have hitherto been considering mainly deciduous trees. In evergreens the conditions are in many respects different. It is generally said that leaves drop off in the autumn because they die. This, however, is not strictly correct. The fall of the leaf is a vital process connected with a change in the cellular tissues at the base of the leaf-stalk. If the leaves are killed they soon they do not drop off. Sir John illustrated this by some twigs which he had purposely broken in the summer; before the fracture the leaves had been thrown off, above they still adhered, and so tightly that they could support a considerable weight. In evergreen trees the conditions are in many respects very different. It is generally supposed that the leaves last a complete year. Many of them, however, attain a much greater age: for instance, in the Scotch fir, three or four years; in the spruce and silver, six or seven; in the yew even longer. It follows from this that they require a tougher and more lasting texture. When we have an early fall of snow our deciduous trees are often much broken down; glossy leaves have a tendency to throw it off, and thus escape, hence evergreen leaves are very generally smooth and glossy. Again, evergreen leaves often have special protection either in an astringent or aromatic taste, which renders them more or less inedible; or by thorns and spines. Of this the holly is a familiar illustration; and it was pointed out that in old plants above the range of browsing quadrupeds, the leaves tend to lose their spines and become unarmed. The hairs on leaves are another form of protection; on herbs the presence of hairs is often associated with that of honey, as they protect the plants from the visits of creeping insects. Hence perhaps the tendency of water species to become glabrous, *Polygonum amphibium* being a very interesting case, since it is hairy when growing on land, and smooth when in water. Sir John then dealt with cases in which one species mimics another, and exhibited a striking photograph of a group of stinging nettles and dead nettles, which were so much alike as to be hardly distinguishable. No one can doubt that the stinging nettle is protected by its poisonous hairs, and it is equally clear that the innocuous dead nettle must profit by its similarity to its dangerous neighbour. Other similar cases were cited.

He had already suggested one consideration, which in certain cases determined the width of leaves; but there were others on which it was due to different causes, one being the attitude of the leaf itself. In many genera with broad and narrow-leaved species, drosera and plantago, for instance, the broad leaves formed a horizontal rosette, while the narrow ones were erect upwards. Fleshy leaves were principally found in hot and dry countries, where this peculiarity had the advantage of offering a smaller surface, and therefore exposing the plant less to the loss of water by evaporation.

Sir John then passed to aquatic plants, many of which have two kinds of leaves: one more or less rounded, which float on the surface; and others cut up into narrow filaments, which remain below. The latter thus presents a greater extent of surface. In air, however, such leaves would be unable to support even their own weight, much less to resist any force such as that of the wind. In perfectly still air, however, for the same reason, finely divided leaves may be an advantage, whereas in

SOCIETIES AND ACADEMIES

LONDON

Royal Society, February 12.—"On Underground Temperatures, with Observations on the Conductivity of Rocks, on the Thermal Effects of Saturation and Imbibition, and on a Special Source of Heat in Mountain Ranges." By Joseph Prestwich, M.A., F.R.S., Professor of Geology in the University of Oxford.

The author remarks on the difference of opinion between physicists and geologists respecting the probable thickness of the outer crust of the earth—the former on the strength of its great rigidity and the absence of tides, contending for a maximum thickness and comparative solidity of the whole mass; while the latter, in general, on the evidence of volcanic action, the crumpling and folding of the strata in mountain ranges, its general flexibility down to the most recent geological times, and the rate of increase of temperature in descending beneath the surface, contend for a crust of minimum thickness as alone compatible with these phenomena.

The question of underground temperature, which is a subject equally affecting the argument on both sides, had engaged the author's attention in connection with an inquiry respecting volcanic action, and he was induced to tabulate the results to see how far the usually received rates of increase were affected by various interfering causes—not that most of them had not received due attention, but it was a question whether sufficient allowance had been made for them.

Although Gensanne's first experiments were made in 1740, and others were subsequently made by Daubuisson, Saussure, and Coudier, in coal and other mines, it was not until the construction of deep artesian wells commenced in the second quarter of this century, and Walferdin introduced his overflow thermometer, and precautions were taken against pressure, that the more reliable observations were made and admirably discussed by Arago. The Coal Commission of 1866 collected a mass of important evidence bearing on the question, and in 1867 a Committee of the British Association was appointed to collect further information. Under the able superintendence of Prof. Everett, a series of valuable experiments with improved instruments has

been made, and full particulars published in the *Annual Reports* of 1868-83.

But notwithstanding the precautions taken, and the accuracy of the experiments, they present very wide differences in the thermometric gradient, ranging from under 30 to above 120 feet per degree F. Consequently different writers have adopted different mean values. On the Continent one of 30 m. per degree C. has been commonly adopted, while in this country some writers have taken a mean of 50 feet per degree, and others of 60 feet or more. The object which the author has in view is to see whether it is not possible to eliminate the more doubtful instances, and to bring the probable true normal gradient within narrower limits. In so doing he confines himself solely to the geological side of the inquiry.

In a general list, Table I., he gives all the recorded observations in the order of date. The list embraces observations at 550 stations in 248 localities. The most reliable of these he classifies under three heads in Tables II., IIL, and IV.

(1) Coal mines.
(2) Mines other than coal.
(3) Artesian wells and bore-holes.

To which tunnels are added in a supplement.

The author then proceeds to point out that the gradients given in many of the earlier observations were wrong in consequence of neglecting the height of the surface, and from the exact mean annual temperature of the locality not being known. They also differed amongst themselves from taking different surface temperatures, and starting from different datum levels. To these he endeavours to assign a uniform value.

The essential differences in the results in several tables depend, however, upon dissimilar geological conditions, which unequally affect the conductivity of the strata, and disturbing causes of different orders. In the mines the latter are :—

(1) The currents established by ventilation and convection.
(2) The circulation of underground waters.
(3) Chemical reactions.
(4) The working operations.

And in artesian wells—

(1) The pressure of the water on the thermometers.
(2) Convection currents in the column of water.

In the latter experiments pressure has been thoroughly guarded against, but against the subtle influence of the other causes, though long known, it is more difficult to guard.

Coal Mines.—The author then proceeds *seriatim* with each subject, commencing with coal-mines. In these he shows that ventilation and convection currents have rendered many of the results unreliable, as he shows to have been the case in the well-known instance of the Dukinfield coal pit. The circulation of air in coal pits varies from 5000 to 150,000 cubic feet per minute, and tables are given to show how this variously affects the temperature of the coal at different distances from the shaft, *though on the same level*. As a rule, the deeper the pit the more active is the ventilation, and therefore the more rapid the cooling of the underground strata. In some pits the indraughted air has been known to form ice, not only in the shaft, but icicles in the mine near the shaft.

The cooling effects of ventilation are shown to begin immediately that the faces of the rock and coal are exposed, and as the hotter (and deeper) the pit, and the more gassy the coal, the more active is the ventilation, so these surfaces rapidly undergo a cooling until an equilibrium is established between the normal underground temperature and the temperature of the air in the gallery. Judging by the effects of the diurnal variations on the surface of the ground, it is clear that an exposure of a few days must, when there is a difference of 10° to 12° or more between the air in the gallery and the normal temperature of the rock, tell on the exposed coal and rock to the depth of 3 to 4 feet —the usual depth of the holes in which the thermometers are placed. The designation of "fresh open faces" is no security, as that may mean a day or a week, or more. The author considers also that so far from the length and permanence of the experiment affording security, he is satisfied on the contrary that those experiments in which it is stated that the thermometer has been left in the rock for a period of a week, a month, or two years without any change of temperature, affords *prima facie* evidence of error, inasmuch as it shows that the rock has so far lost heat as to remain in a state of equilibrium with the air at the lower temperature in constant circulation.

Another cause of the loss of heat which requires some notice is the escape of the gas, which exists in the coal either in a highly compressed, or, as the author thinks more probable, in a liquid state. A strong blower of gas has been observed to render the coal sensibly cooler to the touch. In another case whereas the temperature of the coal at the depth of 1260 feet was 74° F., at the greater depth of 1588 feet in a hole with a blower of gas it was only 62°. One witness observed that "the coal gives out heat quicker than the rock." There is generally a difference of 2° or 3° between them.

On the other hand, the coal and rocks when crushed and in "creeps" acquire a higher temperature owing to the liberation of heat.

The effects of irregularities of the surface on the underground isotherms, although unimportant in many of our coal-fields, produce very decided results in the observations on the same level in the mines among the hills of South Wales. Sections are given to show how the temperature rises under hills and falls under valleys, showing that it is often essential to know not only the depth of the shaft but the depth beneath the surface at each station where the experiments are made.

The author therefore considers that to assign a value to an observation we should know (1) height of pit above sea-level, (2) the exact mean annual temperature of the place ; (3) depth beneath the surface of each station ; (4) distance of the stations from the shaft ; (5) temperature and columns of air in circulation ; (6) length of exposure of face ; (7) whether or not the mine is gassy. The dip of the strata and the quantity of water are also to be noted.

Very few of the recorded observations come up to this standard, and the author has felt himself obliged to make a very restricted selection of cases on which to establish the probable thermometric gradient for the coal strata. Amongst the best observations are those made at Boldon, North Seaton, South Hetton, Rosebridge, Wakefield, Liége, and Mons. These give a mean gradient of 49½ feet for each degree F. The bore-holes at Blythswood, South Balgray, and Crossness give a mean of 50·8 feet.

Mines other than Coal.—The causes affecting the thermal conditions of these mines are on the whole very different to those which obtain in coal mines. Ventilation affects both, but in very unequal degrees. In mineral mines it is much less active, and the cooling effects are proportionately less. On the other hand the loss of heat by the underground waters in mineral mines is very important. In some mines in Cornwall, the quantity of water pumped up does not exceed 5 gallons, while in others it amounts to 200 gallons per minute. The Dolcoath mine used to furnish half a million gallons of water in the twenty-four hours, while at the Fuel Abraham mine it reached the large quantity of above 2,000,000 gallons daily. The rainfall in Cornwall is about 46 inches annually, and of this about 9 inches pass underground. In the Gwennap district, where 5500 acres were combined for drainage purposes, above 20,000,000 gallons have been discharged in the twenty-four hours from a depth of 1200 feet. This water issues at temperatures of from 60° to 68°, or more than 12° above the mean of the climate, showing how large must be the abstraction of heat from the rocks through which the waters percolate.

Hot springs are not uncommon in these mines. They are due to chemical decomposition, and to water rising in the lodes and fissures from greater depths. The decomposition which goes on in the lodes near the surface, and whereby the sulphides of iron and copper are reduced ultimately to the state of peroxides and carbonates of those metals, is a permanent cause of heat, especially apparent in the shallower mines. On the other hand, where the surface waters pass rapidly through the rocks, they lower the temperature and give too low readings.

While ventilation, therefore, reduces the rock temperatures, the water which percolates through the rock, and more especially through the veins and cross-courses, sometimes raises, and at other times lower, the temperature of the underground workings. Mr. Were Fox, who for many years made observations on the underground temperature of the Cornish mines, gave the preference to the rocks ; while Mr. Henwood, an observer equally experienced and assiduous, considered that the underground springs gave surer results. Both were of course fully alive to all the precautions that in either case it was necessary to take to guard against these interferences.

Taking ten of the most reliable of Mr. Henwood's observations at depths of from 800 to 2000 feet, the mean gives a thermometric gradient of 42·4 feet per degree, but Mr. Henwood himself gives us the mean of 134 observations to the depth of

200 feet, a gradient of 41·5 feet to the experiments in granite, and of 39 feet to those in slate.

Taking the experiments of Mr. Fox in eight mines, varying in depth from 1100 to 2100 feet, the mean of the experiments made in the rock gave a gradient of 43·6 feet per degree, or for the mean of the two observers we have a gradient of 43 feet per degree.

For the foreign mines, in the absence of fuller data, and especially failing in information of the depth of the station beneath the surface, which in the hilly district of Freiberg and Hungary introduces an element of great uncertainty, it is impossible to arrive at any safe conclusion.

Artesian Wells and Borings.—This class of observations presents results much more uniform, and whereas the mines observations were made, the one in crystalline, and the other in unaltered Palæozoic rocks, the wells are, with few exceptions, either in the softer and less coherent rocks of Cretaceous, Jurassic, and Triassic age, which are much more permeable, and, as a rule, much less disturbed.

The causes of interference are mainly reduced to pressure on the instruments and convection currents. The early experiments, where no precautions were taken against these, are, with few exceptions, unreliable, and must be rejected. The larger the bore-hole, the greater the risk of convection-currents, and Prof. Everett has shown that in many cases of deep and large artesian borings, the water which lodges in them is reduced to a nearly uniform temperature throughout the whole depth by the action of these currents. In the deep boring at Sperenberg, before the introduction of plugs to stop these currents, it was found that the temperature near the top of the bore was rendered 4°·5 F. too high, and at the bottom, at a depth of 3390 feet, 4°·6, if not 6°·7, too high by the currents.

Taking the bore-holes in which the water does not overflow, and where, owing to the precautions against these sources, such as those of Kentish Town, Richmond, Grenelle, Sperenberg, Pregny, and Ostend, we get a mean gradient of 51·9 feet per degree.

Overflowing artesian wells should, if we were sure of all the conditions, give the best and most certain results. Taking those where the volume of water is large, and the observations made by competent observers, as in the case of the wells of Grenelle, Tours, Rochefort, Mondorff, Minden, and others, we obtain a mean of 50·2 feet, or, taking the two sets of wells, of 51 feet per degree.

The author, however, points out a source of possible error in those wells, arising from a peculiarity of tubage which requires investigation, and owing to which he thinks the water may suffer a loss of heat in ascending to the surface.

With respect to the extra-European wells, more particulars are required. It may be observed, however, that the wells in the Sahara Desert, which were made by an experienced engineer accustomed to such observations, the mean of eleven overflowing wells, at depths of from 200 to 400 feet, gave 36 feet per degree.

Tunnels.—For the Mont Cenis Tunnel, allowing for the convexity of the surface, Prof. Everett estimates the gradient at 79 feet, and for the St. Gothard, 82 feet per degree. But Dr. Stapff found in the granite at the north end of the tunnel a much greater heat and more rapid gradient, for which there seemed no obvious explanation. Though this axis of the Alps is of late Tertiary date, the author points out that it cannot be due to the protrusion of the granite, as the Swiss geologists have shown that the granite was in its present relative position and solidified before the elevation of this last main axis of the Alps, and he suggests that the higher temperature may be a residue of the heat caused by the intense lateral pressure and crushing of the rocks which accompanied that elevation, for in the crushing of a rigid material such as rock almost the entire mechanical work reappears as heat.

Conductivity of the Rocks. Effects of Saturation and Imbibition.—Some of the apparent discrepancies in the thermometric gradients are no doubt due to differences in the conductivity of the rocks. Applying the valuable determinations of Profs. Herschel and Lebour to the groups of strata characterising the several classes of observations, the following results are obtained :—

	Mean conductivity k	Mean resistance r
(1) Carboniferous strata	·00488 ...	275
(2) Crystalline and schistose rocks ...	·00546 ...	184
(3) Triassic and Cretaceous strata ...	·00235 ...	465

From this it would appear that the conductivity of the rocks associated with the mineral mines is twice as great as that of the artesian wells class. But all the experiments, with the exception of three or four, were made with blocks of dried rocks, and those showed a very remarkable difference ; thus, for example, dry New Red Sandstone gave k·00250, whereas when wet it was increased to k·00600. The author remarks that as all rocks below the level of the sea and that of the river valleys are permanently saturated with water, dry rocks are the exception and wet rocks the rule in nature, consequently the inequalities of conductivity must tend to disappear. The power of conduction is also greater along the planes of cleavage or lamination than across them, and therefore the dip of the strata must also exercise some influence on the conductivity of different rocks and "massifs." With respect to the foliated and schistose rocks, M. Jannettaz has shown that the axes of the thermic curve along and across the planes of foliation and cleavage are in the following proportions :—

Gneiss of St. Gothard	1 : 1·50
Schists of Col Voza...	1 : 1·80
Cambrian slates, Belgium	1 : 1·98

This cause will locally affect the rock masses.

Conclusion.—The author deduces from the three classes of observations a general mean thermic gradient of 48 feet per degree F., but he considers this only an approximation to the true normal gradient, and that the readings of the coal-mines and artesian-well experiments are, owing to the causes he enumerates, still too high. He also discusses the question whether or not the gradient changes with the depth. His own reduction of the observations gave no result, but he points out that in all probability the circulation of water arising from the extreme tension of its vapour is stayed at a certain depth ; while it has been shown experimentally that the conductivity of iron diminishes rapidly as the temperature increases, and this may possibly in a different degree apply to rocks. If, therefore, there is any change, these indications would be in favour of a more rapid gradient.

Taking all these conditions into consideration, the author inquires whether a gradient of 45 feet per degree would not be nearer the true normal than even the one of 48 feet obtained by the observations.

Linnean Society, February 19.—Prof. P. Martin Duncan, F.R.S., Vice-President, in the chair.—The Rev. L. Martial Klein was elected a Fellow.—Mr. Thiselton Dyer exhibited and made remarks on specimens of the peculiar Chinese "square bamboo" (*Bambusa quadrangularis*, Fenzi), and of articles made from the so-called "hairy bamboo" (probably *Dendrocalamus latiflorus*, Munro), sent from Wenchow to the Kew Museum by Dr. Macgowan.—Mr. T. Christy afterwards drew attention to silk fibres received from Auckland, New Zealand.—An abstract of Part iii. of the Rev. A. Eaton's monograph on the Mayflies (Ephemeridæ) was read by the Secretary. In this, the fourth series of group 2 of the genera are dealt with. Among representatives of Section 9, *Cloën* is distinguished by absence of hind wings, *Callibætis* by costal projection and cross-veinlets of its broad obtuse hind wings, *Baetis* by small or absence of costal projection and deficiency of cross veinlets, and *Centroptilum* by extreme narrowness of hind wings and slenderness of costal projection. The distinctive characteristics of sections 10 and 11 of the genera are also taken into consideration, and full descriptions of many new species given.—Then followed notes on the European and North American mosses of the genus *Fissidens*, by Mr. W. Mitten. Referring to the more recent important contributions of Dr. Braithwaite's British Moss-Flora, and Messrs. Lesquereux and James's North American Mosses, and taking into account definitions of older writers, such as Dillenius, Hedwig, Swartz, and others, Mr. Mitten endeavours to arrange the entire group afresh, partly in a tabular form, and afterwards supplementing this by notes on the individual species.—A paper was read by Prof. P. M. Duncan on the anatomy of the Ambulacra of the recent Diadematidæ. The author described the arrangement of the compound plates of the genera of *Diadema*, *Echinothrix*, *Centrostephanus*, *Atropyga*, *Micropyga*, and *Aspidadiadema*. The first three genera have triplets, consisting of primaries, the adoral and aboral plates being low and broad, and the second, or central plate, being a large primary. Nea, the peristome there is deformity of this typical arrangement and in *Echinothrix* a demiplate may enter, but it is never the second plate. In *Astropyga* the triplets are arranged so that the

majority are on the *Diadema*-type, and the exceptions were recorded. The structure of the triplets of *Micropyga* is unique, and the arrangements, leaving out the position of the pores, is somewhat like that of *Cyclopleurus*. *Aspidodiadema*, as has been explained by A. Agassiz, is like *Chiarts* in its ambulacra.

Mathematical Society, February 12.—J. W. L. Glaisher, F.R.S., President, in the chair.—Miss Emily Perrin, Ladies College, Cheltenham, was elected a Member, and Mr. J. Griffiths was admitted into the Society.—Mr. Tucker read the following papers:—"Sur les Figures semblablement Variables," by Prof. J. Neuberg; on the extension of Ivory's and Jacobi's distance-correspondences for quadric surfaces, by Prof. J. Larmor; and some properties of a quadrilateral in a circle the rectangles under whose opposite sides are equal, by R. Tucker. Messrs. Jenkins and S. Roberts spoke on the subject of the first paper. A clear idea of Mr. Tucker's communication will be obtained by drawing a figure for the following particular case:—Take a quadrilateral, $ABCD$, in a circle, with its angles A, $B = 58°$, $112°$ respectively, and AB (the unit of length) equal the side (in this case) of the inscribed square. Let $BC = \lambda$, $CD = \mu$, $DA = \nu$; then if two sets of lines drawn in the same *sense* with the respective sides from the two ends make with those sides (in the particular case) angles of 38°, these lines will intersect in two sets of 4 lines in P, P' (analogous to the Brocard points of a triangle), and in four sets of 2 lines in F, G, H, K. The quantities λ, μ, ν, are so related that $\lambda s = \mu$, hence we see that all such quadrilaterals have the rectangles under their opposite sides equal. The six points lie on a circle which also passes through the circum-centre (O), point of intersection (E) of the diagonals AC, BD, and through the mid-points M, L of those diagonals. In fact, since OE is a diameter of this new circle, the mid-points of any chord of the circum-circle which passes through E lies on the small circle. P, P' are the foci of an ellipse inscribed in $ABCD$. Further properties are $OP = OP'$, $AP.BP.CP.DP = AP'.BP'.CP'.DP'$, and many other metrical and angular relations belong to the above collection of points. If instead of 38° we take ϕ, then ϕ is found by the equation $\operatorname{cosec}^2\phi = \operatorname{cosec}^2 A + \operatorname{cosec}^2 B$. The side AB subtends at an opposite vertex an $\angle\theta_1$, such that $\cot\theta_1 = \cot\phi - \cot A - \cot B$, with similar values for the other angles. The circum-radius (R) is found by—

$$2R^2 = (\cot\phi - \cot A)(\cot\phi - \cot B),$$

and that of the small circle (ρ) by

$$2\rho = R \sec\phi \sqrt{\cos 2\phi}.$$

Relations connecting the θ set and ϕ with the Brocard angles of the 4 constituent-triangles are easily obtained in a neat form. If through E lines are drawn parallel to the sides cutting them in eight points, these points lie on a circumference which has many properties analogous to those of the "$T.N.$" circle of a triangle. If ρ' is its radius, then $\rho^2 + \rho'^2 = R^2/2$: the eight points from two equal inscribed quadrilaterals similar to the given figure, and whose sides make the same angle ϕ with the given sides.

Geological Society, January 28.—Prof. T. G. Bonney, F.R.S., President, in the chair.—Frederick John Cullis, Henry Dewes, Henry Hutchings French, Jacob Hort Player, and the Hon. Donald A. Smith, were elected Fellows, and Prof. F. Fouqué, of Paris, and Dr. Gustav Lindström, of Stockholm, Foreign Correspondents of the Society.—The President called attention to the great loss the Society had sustained in the sudden and unexpected death of Dr. J. Gwyn Jeffreys, F.R.S., &c., who had been for twenty-one years continuously a Member of the Council, and for fourteen years of that time had performed most valuable services to the Society as Treasurer.—The following communications were read:—The Boulder Clays of Lincolnshire: their geographical range and relative age, by A. J. Jukes-Browne, F.G.S. The author commenced by referring to the late Mr. Searles V. Wood's papers on the glacial beds of Yorkshire and Lincolnshire, and stated, as the result of his own investigations, that two distinct types of boulder clay occur in Lincolnshire: (1) the gray or blue clay; (2) the red and brown clays, the former undoubtedly an extension of the upper or chalky boulder clay of Rutland and East Anglia, while the second includes the purple and Hessle clays of Mr. S. V. Wood. These two types of boulder clay are very rarely in contact with each other. The brown boulder clays of East Lincolnshire rest upon a broad plain of chalk, which appears to terminate westward in a concealed line of cliff, this cliff-line coinciding with the strike of the slope which descends from the chalk wolds to the boulder clay plateau by which they are bordered. The present boundary line of the boulder clay runs along this slope for long distances, though in many places the clay has surmounted the slope and caps the hills to the west of it. From Louth the main mass of the "brown clay" is bounded by a line drawn through Wyham, Hawerby, Laceby, and Brocklesby to Barrow and Barton on Humber, sweeping around the north end of the Lincolnshire wolds and occurring on both sides of the Humber. Previously to the author's inspection of this district no purple or Hessle clay had been discovered west of South Ferriby, and these clays were supposed to be entirely absent on the western side of the wolds. The officers of the Survey have, however, mapped several tracts of such clay in the valley of Ancholme. It occupies the surface at Hackthorne, Winterton Holme, Winterton, and Winteringham. It probably underlies the alluvium of the Ancholme near and south of these places, and occurs again at higher levels in the neighbourhood of Brigg. South of Brigg it has been seen at low levels on either side of the valley of the Ancholme, as far as Bishop's Bridge near Glentham. Beyond this point it was not traceable in the Ancholme valley, but south of Market Rasen patches of reddish-brown clay, mottled with gray, and containing small flints and pebbles of chalk, occur, and cap the low ridges separating the valleys of the brooks. Another tract of boulder clay, which the author considers to belong to the same series, occupies the western border of the fenland south-east of Lincoln, what is left of it forming a ridge which runs southward for many miles. It passes eastward beneath the fen deposits; and similar mottled clay was seen in the excavations for the Boston Docks beneath about twenty feet of fen clays, &c., and resting upon blue boulder clay of the "chalky" type. Besides this section at Boston, there are very few places where the two types of clay are in contact, or so near as to afford any evidence as to their relative age. Near East and West Keal, and again near Louth, the "brown clays" are banked against the slopes of hills which are capped with the "chalky clay." The same is the case also near Brigg, where the country seems to have been originally covered by a sheet of the chalky clay, through which valleys were eroded into the Jurassic clays, and the brown (Hessle) clay is found only in these valleys. The author concludes, therefore, that the "Brown-clay series" is of much newer date than the "Ilas and Grey series." In conclusion the author summed up the inferences drawn in the paper, correlated the Basement clay of Holderness with the Chalky clay of Lincolnshire, and suggested that the Purple clay may be confined to the east side of the wolds. The classification he would propose is therefore as follows:—

	Lincolnshire.	Yorkshire.
Newer Glacial.	Hessle clay.	Hessle and upper red clay of coast.
	Purple clay.	Purple clay.
Older Glacial =	Chalky clay.	Basement clay.

—On the geology of the Rio Tinto Mines, with some general remarks on the pyritic region of the Sierra Morena, by J. H. Collins, F.G.S. After briefly describing the geographical position of the Rio Tinto mines and the occurrence at the same of pyritous ores amongst slates and schists which abut against gneissose rocks to the north, and pass under Tertiary beds to the southward, the author proceeded to consider the general characters and associations of the pyrites-deposits, and then gave a general account of the Rio Tinto district. The slates were described, and the fossil evidence recapitulated upon which an Upper Devonian age had been assigned to them. Analyses were furnished to show the changes due to weathering and to infiltration. The various intrusive rocks (syenite, diabase, and porphyries) occurring in the schists were described, and analyses of them given. The sedimentary iron ores and their composition were next noticed, and the author ascribed their formation to deposition in lakes. The masses of pyrites which furnish the principal ores of Rio Tinto were then described, their mode of occurrence in fissures between dissimilar rocks explained, and their formation discussed. The different kinds of ore obtained from the mines were noticed in detail, and several analyses added, giving samples both of the mixed ores and of the pure minerals. The manganese lodes were next described, and shown to be parallel to the pyrites fissures, and frequently to be only branches of the latter. A summary of the author's conclusions as to the stratigraphy of the district, the ore deposits, and the surface-geology was appended.—On some new or imperfectly known Madreporia from the Great Oolite of the counties of Oxford, Gloucester, and Somerset, by R. F. Tomes, F.G.S.

Physical Society, February 14.—Annual General Meeting.—Prof. Guthrie, President, in the chair.—Prof. G. Fuller was elected a Member of the Society.—The President then read the Report of the Council, in which the Society was congratulated upon the number of original communications read—forty-three during the past year. Among the works undertaken by the Society may be mentioned the publication of the first volume of "Joule's Scientific Works"; a second volume, containing accounts of researches conducted by Mr. Joule in conjunction with other scientific men, would be published shortly.—The Treasurer presented a highly satisfactory report.—The Council for the ensuing year was then elected, the result of the election being as follows:—President: Prof. F. Guthrie, Ph.D., F.R.S.; Vice-Presidents (who have filled the office of President): Dr. J. H. Gladstone, Prof. G. C. Foster, Prof. W. G. Adams, Sir W. Thomson, Prof. R. B. Clifton; Vice-Presidents: Prof. W. E. Ayrton, Shelford Bidwell, Lord Rayleigh, Prof. W. C. Roberts; Secretaries: Prof. A. W. Reinold and Walter Baily; Treasurer: Dr. E. Atkinson; Demonstrator: Prof. F. Guthrie; other Members of Council: C. Vernon Boys, C. W. Cooke, Prof. G. Forbes, Prof. F. Fuller, R. T. Glazebrook, Dr. J. Hopkinson, Prof. H. McCleod, Prof. J. Perry, Prof. J. H Poynting, Prof. S. P. Thompson; Honorary Member: Prof. M. E. Mascart.—The customary votes of thanks to the Committee of the Council of Education and to the President, Secretaries, and other officers having been passed, the meeting resolved itself into an ordinary meeting of the Society.—Miss Marks described a new line and area divider. This instrument consists of a hinged rule with a firm joint. The inside edge of each limb is bevelled, and presents a straight edge. One limb is divided on both edges into a number of equal parts, and is fitted by a groove on its outer edge to a plain rule, along which it can slide. To divide a line into a given number of equal parts, the hinged rule is slid along the plain rule till the nth division from the joint is opposite a fixed mark on the plain rule; it is then placed on the paper so that the nth division on the graduated straight edge coincides with one end of the given line, and then opened till the straight edge on the inner edge of the other limb passes through the other extremity. The plain rule is then pressed firmly down and the hinged rule slid along it. As each division of the graduated edge passes the fixed mark, the intersection of the moving edge with the given line is marked, and thus the line is divided into n equal parts. The instrument may be used in this way to draw any given number of equidistant parallel lines between two given points. It may be conveniently used in working out indicator diagrams and measuring areas.—Mr. Walter Baily described certain improvements made in his integrating anemometer, which has been previously described. The improvements consist in the substitution of mechanical counters for electrical ones, as it was found, in the recent observations with the instrument at Kew, that the extra friction of the "contact" was sometimes sufficient to stop the motion. The mechanical counters were found to work satisfactorily in every respect.—Prof. Guthrie showed some specimens exhibiting the similarity of fracture of Canada balsam and glass. The glass had been cracked by heating a metal ring to which it was attached; the Canada balsam had been overheated in a small dish and allowed to cool.

Zoological Society, February 17.—Osbert Salvin, F.R.S., Vice-President, in the chair.—Mr. F. E. Beddard, F.Z.S., read a paper upon the structure of the Cuckoos (Cuculidæ), and pointed out the differences in the pterylosis and the structure of the syrinx in the various forms which he had examined. It was proposed to divide the family into three sub-families: Cuculinæ, Phœnicophainæ, and Centropodinæ.—Mr. F. E. Beddard read a paper upon the heart of *Apteryx*, and called attention to the variations in the condition of the right auriculo-ventricular valve observed in different individuals of this bird.—A communication was read from Mr. M. Jacoby, containing the first part of an account of the Phytophagous Coleoptera obtained by Mr. George Lewis during his second journey in Japan, from February, 1880, to September, 1881.

Geologists' Association, February 6.—W. H. Hudleston, F.R.S., in the chair.—The annual meeting was held at University College.—The following Officers were elected for the ensuing year:—President: W. Topley, F.G.S., Assoc. Inst. C.E.; Vice-Presidents: Prof. J. F. Blake, M.A., F.G.S., T. V. Holmes, F.G.S., W. H. Hudleston, F.R.S., F.G.S., F.C.S., Henry Hicks, M.D., M.R.C.S., F.G.S.; Treasurer: J. Hopkinson, F.G.S., F.L.S.; Secretary: John Foulerton, M.D., F.G.S.; Editor: Prof. G. S. Boulger, F.L.S., F.G.S.; Librarian: J. Bradford, F.G.S.; Council: J. Logan Lobley, F.G.S., F.R.G.S., Ed. Litchfield, A. C. Maybury, F.G.S., J. Love, F.G.S., F.R.A.S., W. H. Bartlett, F.G.S., T. Davis, F.G.S., J. J. H. Teall, F.G.S., R. Meldola, F.C.S., J. Slade, F.G.S., J. S. Gardner, F.G.S., Prof. T. Rupert Jones, F.R.S., B. B. Woodward, F.G.S.—Prof. T. R. Jones, F.R.S., gave an address on Foraminifera, recent and fossil, and Mr. F. W. Rudler one on some points in connection with volcanic action; both were illustrated by lantern views exhibited by Mr. G. Smith.—Many instructive objects were exhibited, amongst them a series of Palæolithic implements from France, Spain, and England, by Dr. J. Evans, F.R.S.

EDINBURGH

Royal Society, February 2.—Mr. Thomas Stevenson, President, in the chair.—The President delivered an address, in which he discussed the erection of training-walls at the mouth of the Mersey. He would strongly condemn such a procedure, asserting that the inevitable result would be the silting up of the approaches to Liverpool.—Prof. Tait submitted a paper on condensation and evaporation. He pointed out that the present mode of treating the conditions of a liquid in presence of its vapour were not rigorous, inasmuch as the pressure is undoubtedly different in the two parts, while in the surface-layer between them there is a complex form of stress. If attention be confined to the isothermals of the interior parts of a liquid, or of its vapour, the present method will apply rigorously. With this proviso the isothermals under the critical point consist of two parts separated by an asymptote—one belonging to the liquid, the other to the vapour. This accords with the fact that liquids can be subjected to hydrostatic tension, and that Aitken has shown that true vapour cannot be condensed without a nucleus.—Mr. John Rattray, of the Granton Marine Station, communicated a note on Ectocarpus.—The Rev. J. M. Macdonald exhibited some specimens from Philadelphia which had the appearance of large vegetable fossils. Mr. John Murray and Prof. Duns pronounced them to be merely inorganic accretions around reeds.

Mathematical Society, February 13.—Mr. A. J. G. Barclay, President, in the chair.—Prof. Tait communicated a note on a plane strain, which was read by Mr. W. Peddie; Dr. Muir gave an account of a paper by Mr. P. Alexander on Boole's proof of Fourier's double integral theorem, and afterwards enunciated several theorems of his own on the arbelos; Mr. Peddie discussed reflected rainbows; Mr. Allardice gave a note on spherical geometry: and Mr. A. Y. Fraser made some remarks on a problem in plane geometry.

CAMBRIDGE

Philosophical Society, February 2.—Prof. Foster, President, in the chair.—Prof. C. S. Roy, M.A., was elected a Fellow.—The following communications were made:—On the Zeta-function in elliptic functions, by Mr. J. W. L. Glaisher.—On a certain atomic hypothesis, by Prof. K. Pearson. Communicated by Mr. H. T. Stearn.—On a Young's eriometer, by Mr. R. T. Glazebrook.

PARIS

Academy of Sciences, February 16.—M. Bouley, President, in the chair.—On the inaccuracies committed in the employment of the usual formulas in the reduction of the polar stars and in determining the astronomic collimation. The correct terms required to remove these errors. Method of observing the polar stars at any meridian distance, by M. Lœwy.—Description of the nervous system of *Ancylus fluviatilis*, by M. H. de Lacaze-Duthiers.—On the order of appearance of the first vessels in the leaves of the cruciferæ; third part, *Crambe maritima*, *juncea*, and *cordifolia*, by M. A. Trécul.—Experiments on some phenomena of the movement of water in an apparatus employed to raise the liquid by means of a mechanical fall without piston or lifting valve, by M. A. de Caligny.—On the resistance of keels in connection with the velocities of 20 and 21 knots an hour recently obtained without special extra motor power, by M. A. Ledieu.—On the oïdium, *Phoma vitis*, mildew (*Peronospora viticola*), and some other cryptogamic diseases prevalent for some years past in the European vineyards, by M. H. Marès.—On the density and figure of the earth, by Gen. L. F. Menabrea. The author's researches tend to confirm the anticipations of Newton that the mean density of the earth would be found to lie between five and six times that of water.—On the development of the vascular apparatus, and of the reproductive organs

in the tomatulæ, by M. Edm. Perrier.—Extraction of the green colouring matter of leaves; definite combinations formed by chlorophyll, by M. Er. Guignet.—On some theorems in algebra, by M. Stieltjes.—On the heating power of coal-gas in various states of dilution, by M. A. Witz. From his experiments the author infers that the complete combustion of gas requires a dilution of over six volumes of air, the effect of the dilution thus being the reverse of what might be supposed *a priori*.—On the laws of solution, by M. H. Le Chatelier. From his researches the author concludes that solubility increases with the temperature for bodies whose solution absorbs heat, decreases for those that liberate heat, and remains unchanged when the heat of solution is null.—On the solution of the carbonate of magnesia by carbonic acid, second note, by M. R. Engel.—On a crystallised hydrate of phosphoric acid, by M. A. Joly.—Note on the cellular structure of cast steel, by MM. Osmond and Werth.—On glycol, its preparation and solidification, by M. G. Bouchardat. A very pure preparation of glycol, obtained by a solution of carbonate of potassa acting on the bromide of ethylene, was found to boil at 198° C., and to solidify at temperatures varying from - 11°·5 to - 25°.—Note on monochlorhydric glycol, by M. G. Bouchardat.—Action of the diastase of malt on natural starch, by M. L. Brasse.—On the rotatory power of the solutions of cellulose in Schweizer's liquid, by M. Alb. Levallois.—Observations regarding the organisms to which fermentation is due; claim of priority of discovery in connection with some remarks of M. Pasteur on a recent note of M. Duclaux, by M. A. Béchamp.—Note on the anatomical structure and classification of *Halia priamus* (Risso), by M. J. Poirier.—On the anatomy of the brachiopods of the genus Crania, by M. Joubin.—On the nervous system of a Fissurella (*F. alternata*), by M. L. Boutan.—On the origin of the metalliferous ores existing on the periphery of the central plateau of France, and especially in the Cevenne highlands, by M. Dieulafait.—On the results of M. Sokoloff's studies on the formation of sandy dunes in Central Asia, by M. Venukoff.

BERLIN

Physiological Society, January 21.—Dr. von Monakow, referring to his anatomical investigations of the brain, communicated an account of those relating to the central origin of the optic nerve. He had enucleated on one or both sides the bulbus in young rabbits and cats, and, after an interval of some months, examined the changes which had set in as a result of that violence done to the brain. In each case he found regular ascending atrophy capable of being traced up to the origin of the nerves. By this means he had been able to recognise as central original spots of the nervi optici the corpus geniculatum externum, the pulvinar and the anterior corpora quadrigemina. The corpus geniculatum and the pulvinar consisted of large multipolar cells, between which lay a gray medullary substance, which, on being coloured with carmine, showed a particularly strong tinge. After the enucleation, atrophy of the gray medullary substance was observed in both, while the cells remained altogether intact. On colouring with carmine, the somewhat shrunken organs appeared much paler than in the normal state. In the corpora quadrigemina five different layers of small and large cells and fibrous bands were distinguished. Of these the three innermost layers lying towards the ventricle remained intact, while the two exterior cellular layers were atrophied or were altogether wanting. The degeneration and disturbance of growth after the enucleation of the bulbus had not, however, extended beyond these primary centres of the optic nerve. Dr. von Monakow had, furthermore, removed particular parts of the cerebral cortex lying within Munk's sphere of vision, and the degeneration and atrophy which succeeded this injury, and, extended peripherically, could be followed through Gratiolet's fibres on to the three centres of optic nerves above mentioned, the corpus geniculatum externum, the pulvinar and the anterior corpora quadrigemina (*Vierhügeln*), and beyond these centres as far as the tractus opticus and the optic nerves. It was an interesting fact that after the injury of the cerebral cortex the degeneration of the three centres of optic nerves was of a different character from that which set in after the peripherical enucleation. The corpus geniculatum and the pulvinar were now altered in such a manner that it was mainly the cells which either showed degeneration or were entirely wanting. In the anterior corpora quadrigemina, likewise, it was other layers—namely, the third medullary layer and the larger cells—which were overtaken by degeneration. The speaker had had the opportunity, in making a dissection, of substantiating on a man who had long been suffering from diseased retina, that the degeneration in the case of man propagated itself centrally towards the three centres before-mentioned—just as much as in the case of the rabbits operated on.—Dr. Weyl spoke on casein, which took quite an exceptional place among albuminous bodies. According to the most recent researches albuminous bodies contained only O, H, N, C, and S, but no phosphorus, and might be divided into (1) albumins or albuminous bodies soluble in water; (2) globulins, insoluble in water, but soluble in solution of common salt; (3) proteins, soluble neither in water nor solution of common salt, but in diluted alkalis. Finally, a fourth group of albuminous bodies was formed by such as were soluble in none of those reagents, but, except in this one characteristic, had no affinity to each other, such as fibrin, amyloid, casein, &c. Casein had hitherto been identified only in milk. It was an albuminous body, because under the agency of diluted muriatic acid and pepsin it yielded a peptone, and, besides, precipitated an insoluble substance, which may be classed among the nucleins. Casein contained phosphorus, and so was distinguished from all other albuminous bodies. In order to the demonstration of casein and its quantitative determination in milk, Dr. Weyl had, in conjunction with Dr. Frentzel, adopted a new and less detailed process than that of Prof. Hoppe-Seyler so universally introduced into practice. This new process consisted in diluting the milk threefold and reducing it with highly diluted sulphuric acid (1 : 1000). Thereupon a flaky precipitate at once segregated itself, which could be filtered off and weighed. The precision of this method was equal to that of Hoppe-Seyler's, and by means of it Dr. Weyl and Dr. Frentzel had begun to study quantitatively the transformation of casein into pepton and nuclein. The speaker hoped to be able soon to make communications regarding the result of this investigation.—Dr. Rossel had examined the nuclein of the yolk, in order to test the assertion of Mr. Miichat that it resembled the nuclein of cell-nuclei, an assertion which lent a chemical support to the views of Prof. His that the granules of the yolk entered as organic elements towards the upbuilding of the embryo, and formed the cell-nuclei. Dr. Rossel had isolated the nuclein of the yolk of hen-eggs, and, on examining it, had found it essentially different from the nuclein of cell-nuclei. While this latter contained the highly nitrogenous organic bases guanin and hypoxanthin, none of these bases were found in the nuclein of the yolk. The nuclein of the yolk was, therefore, essentially different from that of the cell-nuclei, and under the demonstration of this difference the support which, from the chemical side, had been afforded to the view of the transference of granular formations of the yolk into cell-nuclei, fell away.

A MEDICAL NOVEL.

CHARLEY KINGSTON'S AUNT.

A Study of Medical Life and Experience.

By PEN OLIVER, F.R.C.S. Second Edition. Crown 8vo, 6*s*.

"A novel, written by a physician, with a medical student for its hero, would deserve a few words of notice t our hands even if it were of less conspicuous merit than this interesting volume. . . . The plot turns upon highly dramatic incident, but it is well worked out, and the interest is well sustained until the mystery is fully xplained. . . . The scene is laid in one of the best known of our medical schools of London, and old tudents there will have no difficulty in recognising the truth of several of the portraits which are incidentally ketched. Apart from its technical interest, this book will secure attention by its vigorous writing, its many ell-touched pictures of life and character, its clever incidental use of a picturesque and fading rustic dialect, nd its side-references and just compliment to some of the social traits of medical character; . . . with ouches indicating an intimate knowledge of medical society, and a bright insight into some of the best sides f medical life and character."—*British Medical Journal.*

"To every practitioner who wishes to renew the memories of his youth the book may be confidently ecommended as the companion of an idle hour."—*Medical Times.*

"'I want to make your flesh creep,' said the Fat Boy to the old lady at Dingley Dell. That is what Mr. Pen Oliver, author of 'Charley Kingston's Aunt,' wants to do to his readers, and does very effectively in his arly chapters. But there is much besides 'creepiness' in the book: cheery descriptions of old-fashioned nedical-student life, an excellent 'interior' of a common lodging-house, a well-sustained tracking of a mystery, nd much of the soft Suffolk talk by one who evidently knows it well. This single-volume story is one which hould be asked for at Mudie's."—*The World.*

"Charley Kingston has one of the most startling experiences ever accorded to a medical student. This ncident is placed in the foreground of the story where the clever French mystery novelists put the murder The manner of telling the tale reminds one a little of that of Mr. William Gilbert, who used to write such ealistic and powerful stories. This is in our opinion a favourable and flattering criticism."—*Daily News.*

MACMILLAN & CO., LONDON.

WALL PAPERS FREE FROM ARSENIC.

WILLIAM WOOLLAMS & CO., Manufacturing Paper Stainers,

ARE THE ORIGINAL MAKERS OF

ARTISTIC WALL PAPERS, Guaranteed Free from Arsenic.

Sole Address—110, HIGH STREET, MANCHESTER SQUARE, LONDON, W.

May be obtained of all Decorators. Special Prize Medal, Sanitary Institute.

Award of Merit, International Medical and Sanitary Congress. Silver Medal, National Health Society, 1883.

GOLD MEDAL, INTERNATIONAL HEALTH EXHIBITION.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

WALTHAM BROTHERS,

THE NEW PATENT
WOVEN WIRE MATTRESS.

The leading peculiarity of this Mattress is the unique combination of a woven wire central portion with helical springs of great strength and reliable temper, giving advantages possessed by no other make. The helical springs obviate the tendency in all woven wire mattresses to become hollow and so cause sleepers to roll into the middle of the bed.

Illustrated Descriptive Circulars and Price Lists free.

CHORLTON & DUGDALE, MANCHESTER.

Collection of Six Fasciated Stems:—Strawberry, Sweet Pea, Tropæolum, Thistle, Stonecrop, and Celosia, 5s.

Roots of Cucurbita, Spruce Fir Ficus repens. **2s.**

When ordered off the Catalogue (except where special prices are affixed) the prices are as follows:—1-in. inch, 5s. a dozen. 25s. per 50, £2 per 100.

Section of Stem of White Lily (Nymphæa alba), showing Trichoblasts, highly Polish. **1s.**

Mr. PIFFARD'S PATENT COUNTER-SUNK SLIPS are now on Sale. Two sizes are ready, 3/1 and 3/6, at 6d. per dozen. They are thus described in the *Journal of the Royal Microscopical Society*, August 1884:—

PIFFARD'S SLIDES.—Mr. B. Piffard has patented a slide, which is made by forming with a diamond a round recess in an ordinary slide. In this the object is placed, and covered with thin glass. The upper surface of the slide is then perfectly smooth, the cover-glass being even with the slide. There is no danger of the cover-glass and object being knocked off; and the recess causes a very beautiful diffusion of light.

REMITTANCE WITH ORDER. ENLARGED CATALOGUE READY, POST FREE.

B. PIFFARD, HILL HOUSE, HEMEL HEMPSTEAD, HERTS.

13 GOLD MEDALS. **THE "OTTO" GAS ENGINE.** 16 SILVER MEDALS.

OVER 15,000 DELIVERED.

CONSUMPTION of GAS guaranteed to be 25 to 75 % less than ANY other Gas Engine per brake horse-power.

CROSSLEY'S PATENT TWIN ENGINES—
Impulse every Revolution.
The steadiest running Gas Engine yet made.

P.O.O. payable to A. CRISTIN.
Publishing Office, 441, Strand, W.C.

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1200 or £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share being given to those by whose early death there is a *loss* to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the net Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being £333,383.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

Price 5s. Post Free.

KEGAN PAUL, TRENCH, & CO.

Complete in Four Volumes with 2500 Woodcuts, price £7 7s. Cloth, or £8 18s. half-bound in Russia.

URE'S DICTIONARY OF ARTS, MANUFACTURES, and MINES,

containing a Clear Exposition of their Principles and Practice. The Seventh Edition, re-written and enlarged. Edited by ROBERT HUNT, F.R.S., Keeper of Mining Records, assisted by numerous Contributors eminent in Science and familiar with Manufactures.

"The great point in a dictionary like Dr. Ure's is to include all that is really essential without rendering the result too bulky, and consequently too costly. This end, we think, the editor and his staff of eminent contributors have reached in a very satisfactory degree. The seventh edition is a book which no manufacturer, merchant, miner, or technologist should be without."—*Journal of Science.*

THURSDAY, MARCH 5, 1885

ORE DEPOSITS

A Treatise on Ore Deposits. By J. Arthur Phillips, F.R.S., &c. Demy 8vo, pp. 624 and Index; 95 Woodcuts and 1 Plate. (London: Macmillan and Co., 1884.)

A WORK in the English language upon ore deposits has long been wanted, and geologists and mining engineers may be congratulated that one so well qualified to do justice to the subject as Mr. Phillips, undertook the laborious task of writing a general treatise.

Mr. Phillips divides his book into two parts; Part I., occupying one-sixth of the volume, treats of ore deposits in general, and Part II. is devoted to a description of the principal metal-mining regions of the world.

We are glad to see that he admits a wide definition of the term "ore:" "Although perhaps not strictly correct, any material obtained by mining that contains a workable proportion of a metal is often called an ore, even if the whole of the metal be present in the native state." This is a common-sense and practical way of dealing with the question.

The classification of ore deposits is in the main the same as that adopted by Whitney, in his "Metallic Wealth of the United States," thirty years ago. Mr. Phillips divides metalliferous deposits into the following groups:—

I. SUPERFICIAL

a. Deposits formed by the mechanical action of water.
b. Deposits resulting from chemical action.

II. STRATIFIED

a. Deposits constituting the bulk of metalliferous beds formed by precipitation from aqueous solutions.
b. Beds originally deposited from solution, but subsequently altered by metamorphism.
c. Ores disseminated through sedimentary beds, in which they have been chemically deposited.

III. UNSTRATIFIED

a. True veins.
b. Segregated veins.
c. Gash veins.
d. Impregnations.
e. Stockworks.
f. Fahlbands.
g. Contact deposits.
h. Chambers or pockets.

This classification is the only blemish of any importance in the volume, and we greatly regret that the author did not cast off the trammels of tradition and strike out a new line for himself.

In the first place, we are disposed to quarrel with the separation of superficial deposits, as described by Mr. Phillips, from stratified deposits; we do not see how they can be logically separated. Speaking of the old auriferous gravels of the Sierra Nevada of California, the author's words are:—"These, which are sometimes known as *blue gravels*, were formerly believed to be of marine origin, but are now recognised as materials brought down by the agency of currents of fresh water from the mountains high above them and deposited, either in the beds of ancient rivers, or in lake-like expansions of such streams." Surely, therefore, they are stratified. Furthermore, the term "superficial" should have been avoided as misleading, because the student will naturally infer that the chief characteristic of such deposits is that they occur at the surface; but when we find gold- and tin-bearing gravels buried at a depth of more than 100 feet under other strata and lava-flows of Pliocene or Miocene age, and worked as true mines, the word "superficial" seems singularly inappropriate. The author admits that the term "might at first sight appear a misnomer," but defends it on the ground that "a volcanic capping is by no means universal, and the uncovered beds of this age are of the greatest importance to the miner." When Whitney's book was written the name was more in harmony with the facts, as the deep leads had not been discovered; but even then there was nothing to justify the separation of the old alluvia from the class of stratified deposits.

The three subdivisions of the stratified deposits are useful for impressing upon the mind the most important varieties of this class; on the other hand, when we come to the unstratified deposits we consider that the author has been unwisely conservative.

Why should the geologist step in and call certain mineral veins "true," and thereby cast a sort of stigma upon others which do not fit in with his preconceived theories? Mr. Phillips, like most authors, uses the word "true vein" as synonymous with "fissure vein"; but as it appears that many of the sheet-like mineral masses called "lodes" or "reefs" by miners are not filled up cracks, it seems a pity that the worship of the "fissure vein" should be continued.

A useful summary is given of the various hypotheses which have been propounded concerning the genesis of mineral veins, and due attention is paid to the discoveries of Prof. Sandberger, which have an important bearing upon the theory of lateral secretion. The author ultimately concludes that both lateral secretion and the ascension of mineral-bearing waters have contributed to the filling up of fissures with the various minerals now constituting the veins.

Though he keeps up the old subdivision of "segregated veins" as distinct from true veins, Mr. Phillips is justly doubtful whether such a distinction can always be logically maintained.

With reference to the "impregnations," it is probable that some of the most important Cornish tin lodes in granite may be classed under this head, and therefore this subdivision might be made to include a good deal more than the *carbonas*.

The word "Stockwork" is unfortunately consecrated by long usage, and it will not be easy to evict it from mining literature; but it is a pity that no English term has been coined to denote this mode of occurrence. Speaking of Polberrow mine, Mr. Phillips says it "appears to be the only stockwork ever extensively worked in clay slate." This is not the case. The three openworks in Cornwall known as Minear Downs, Mulberry and Wheal Prosper are other instances of stockworks in clay slate. They produced 203 tons of dressed tin ore in 1883, and the excavations are certainly sufficiently large to say that the deposits have been "extensively worked." Henwood's account of Wheal Music (*Trans. Roy. Geol. Soc. Cornwall*, vol. v. p. 98) shows that it was a stockwork in clay slate, worked for copper ore.

It seems a mistake to retain the "fahlbands" among the unstratified deposits. They are pyritiferous beds among metamorphic rocks. At Kongsberg they consti-

tute the *congenial country* and not the deposit worked; whilst the Skutterud fahlbands, which are simply cobaltiferous quartzite and mica schist, deserve a place among the stratified deposits quite as much as the magnetite of Arendal or Philipstad.

In Part II. we consider that Mr. Phillips does good service by giving statistics of the production of ores, in addition to the descriptions of their modes of occurrence. As stated by him in the preface, "This appears to be the only way of accurately expressing the relative importance of different metalliferous regions." This feature of Mr. Phillips's book, apart from anything else, at once renders it more valuable than the works of von Cotta, Grimm, and von Groddeck.

The United Kingdom is so rich in minerals that a large amount of space is very fairly allotted to it, and, though Cornwall receives the lion's share of attention, it must be recollected that it is the birthplace of British mining and the school from which a set of hardy and intelligent miners have been dispersed among all parts of the globe.

Speaking of an issue of carbonic acid gas from the lode at Foxdale Mine in the Isle of Man, the author says (p. 212): "At the present time (1883) in the eastern end of the 185-fathom level, the amount of gas is so large that, although volumes of compressed air are continually being poured in from two air-pipes, the men experience the greatest difficulty in working; and, as candles will not burn, the value of the end can only be determined by the ore brought out." This account is somewhat overdrawn. The gas has been troublesome at times, but not to the extent stated, for we are led to infer that the men worked in the dark. Even a Manxman is scarcely capable of driving levels without a light.

The small value of the metalliferous ores raised in France is remarkable, and the prosperity of the Belgian metal mines appears to be on the wane, as the value of the metalliferous minerals decreased from 563,080*l.* in 1872 to 148,720*l.* in 1881.

The famous mines of the German Empire at Commern, in the Upper and Lower Harz, the Mansfeld district and the Erzgebirge are described at as great a length as the space available in a general treatise will admit, and many interesting and important details are given concerning the mines of Austria, Hungary, Italy, Greece, Scandinavia, Spain, and Russia. The statement, "Spain takes the lead of all other countries in the amounts of lead and quicksilver which it produces," is scarcely accurate, unless Mr. Phillips is referring solely to Europe. The United States are now the greatest producers of lead, and the Californian quicksilver mines have for several years surpassed those of Almaden in productiveness. However, as far as the output of quicksilver last year is concerned, Mr. Phillips is doubtless correct, for statistics published within the last few weeks show that the yield of California in 1884 was only 1089 statute tons, which is less than the average amount produced by Spain.

The account of the metalliferous minerals of the Australasian colonies will be read with interest. Though the output of gold is on the whole decreasing, tin ore has within the last ten years become a great source of wealth. An important discovery is that there are *deep leads*, *i.e.* old tin-bearing alluvia, of Miocene age, and the figure representing the deposit worked by Wesley Brothers at Vegetable Creek, New South Wales, gives a good idea of this mode of occurrence. It is startling to learn that Queensland produced 106,488 tons of tin ore, worth 2,168,790*l.* in 1881; unfortunately for the colony, but luckily for Cornwall, the output of the following year was only 27,312 tons.

It was certainly no easy task for Mr. Phillips to compress into 65 pages an account of the principal metalliferous regions of the United States: but he has succeeded in furnishing a very useful *résumé*, the only fault of which is the meagreness with which it has been illustrated. The metal mines of the United States deserve more than seven woodcuts, and we should like to have seen figures to explain the wonderful deposits at Leadville and on the shores of Lake Superior.

It is to be regretted that apparently there is so little available information concerning the mines of Mexico, a country so highly favoured as far as mineral wealth is concerned. South America, too, has to be treated very summarily.

Excepting for having followed a beaten track in his classification, the author deserves much praise for his work. The descriptions of the metal-mining districts are very good, being based upon personal knowledge and the latest published accounts; both Mr. Phillips and his assistant, Mr. Brough, must be commended for the care with which they have ransacked all sorts of British and foreign publications relating to mining. The references are very full and complete, and much vigilance has been exercised in correcting for the press. Finally, we must congratulate the author upon his excellent index, occupying no less than twenty-five closely-printed pages. This adds greatly to the utility of the book, which will doubtless become the standard work upon ore deposits.

OUR BOOK SHELF

Madagascar and France; with some Account of the Island, its People, its Resources, and Development. By George A. Shaw, F.Z.S. (London: Religious Tract Society, 1885.)

THE incident connected with Mr. Shaw's imprisonment on board a French war-ship at Tamatave will be remembered—an incident for which the French Government had to make substantial amends. Mr. Shaw has been a missionary in Madagascar for many years, and has thus had ample opportunity of gaining a knowledge of the interesting island. To those familiar with the literature of Madagascar the volume will not present much of novelty; it is, however, interesting reading, and contains some of the results of Mr. Shaw's own observations. On the physical geography and ethnology of this country there is nothing new, but Mr. Shaw presents the results of previous investigations clearly and briefly. He in the main adopts the generally-accepted conclusions as to the Malay origin of the bulk of the Malagasy people, though we suspect that the aboriginal Vazimba are greater, and the intercourse between the mainland and the island of much older date than he is prepared to admit. He gives many interesting details as to the industries of the people, their social habits, the progress of Christianity and education, the past history of the island, and other points. A large portion of the volume is occupied with the history of the relations between France and Madagascar, in which he tells the story of his own imprisonment. To the scientific reader the concluding chapters on the fauna, flora, and meteorology of the island will prove useful; they summarise what

known, with some additional facts obtained by servation of himself and his brother missionaries. is a map and a few good illustrations.

Months in the Soudan. By Ernestine Sartorius. don: Kegan Paul and Co., 1885.)

SARTORIUS spent most of her three months in 4 at Suakim, of which her husband, Gen. Sartorius, ommandant. Her book deals chiefly with the events culminated in the disaster of El-Teb. It is mostly ant, gossipy record of the daily life of the town, the alarms created by the attempted raids of the us natives in the district around. It affords a lea of the character of the town and its immediate dings.

s on Agricultural Science and other Proceedings he Institute of Agriculture, South Kensington, lon, 1883-84. (London: Chapman and Hall.)

olume contains abstracts of lectures delivered by a rable number of well-known authorities upon agri- matters. Mr. Carruthers and the late Prof. an give their experiences upon grasses and farm Prof. Wrightson has a paper upon land drainings; anagement and farm crops are treated of by Pro- Huldon and Fream and Mr. Bernard Dyer; Mr. Woods contributes lectures upon Southdown sheep illage; while Mr. Warrington has a contribution e nitrogenous matter in soils; and Mr. Worthing- ith gives some good observations upon corn The names of the authors of the various lectures fficient guarantee of their soundness and worth.

Civilisation and Eyesight

I take too much of your space to discuss at length the limit of resolving-power as depending upon aperture. may be referred to some papers in the *Philosophical* for 1879 and 1880, where he will also find references k of other investigators. I will only say that (as indi- e word *fairly* in my statement) resolution admits of ne word *fairly* in my statement) resolution admits of ress. Doubtless a practised observer would judge a star to be double whose components subtend a decidedly smaller angle than two minutes, but he would not see them separated. I purposely rather understated the case. The higher the visual power of civilised men, the less room is there for savages with eyes of equal aperture to surpass them.

With respect to my short-sightedness in a bad light, I shall be glad if you will publish the accompanying two short papers from the *Cambridge Philosophical Proceedings*. They will show how I was led to make the discovery. RAYLEIGH

"The Use of Telescopes on Dark Nights." By Lord Rayleigh. (From the *Camb. Phil. Proc.*, March, 1882.)

In *Silliman's Journal* for 1881 Mr. E. S. Holden, after quoting observations to a like effect by Sir W. Herschel, gives details of some observations recently made with a large telescope at the Washburn Observatory, from which it appears that distant objects on a dark but clear night can be seen with the telescope long after they have ceased to be visible with the naked eye. He concludes, "it appears to me that this confirmation of Herschel's experiments is important, and worth the attention of physicists. So far as I know there is no satisfactory explanation of the action of the ordinary night-glass, nor of the similar effect when large apertures are used."

It is a well-known principle that no optical combination can increase what is called the "apparent brightness" of a distant object, and indeed that in consequence of the inevitable loss of light by absorption and reflection the "apparent brightness" is necessarily *diminished* by every form of telescope. Having full confidence in this principle, I was precluded from seeking the explanation of the advantage in any peculiar action of the telescope, but was driven to the conclusion that the question was one of apparent magnitude only,—that a large area of given small "apparent brightness" must be visible against a dark ground when a small area would not be visible. The experiment was tried in the simplest possible manner by cutting crosses of various sizes out of a piece of white paper and arranging them in a dark room against a black background. A feeble light proceeded from a nearly turned-out gas-flame. The result proved that the visibility was a question of apparent magnitude to a greater extent than I had believed possible. A distance was readily found at which the larger crosses were plainly visible, while the smaller were quite indistinguishable. To bring the latter into view it was necessary either to increase the light considerably, to approach nearer, or lastly to use a telescope. With sufficient illumination the smallest crosses used were seen perfectly defined at the full distance.

There seems to be no doubt that the explanation is to be sought within the domain of physiological optics. It has occurred to me as possible that with the large aperture of the pupil called into play in a dark place, the focussing may be very defective on account of aberration. The illumination on the retina might then be really less in the image of a small than in the image of a large object of equal "apparent brightness."

"On the Invisibility of Small Objects in a Bad Light." By Lord Rayleigh. (From the *Cambridge Phil. Proc.*, Feb., 1883.)

In a former communication to the Society (March 6, 1882) I made some remarks upon the extraordinary influence of apparent magnitude upon the visibility of objects whose "apparent brightness" was given, and I hazarded the suggestion that in consequence of aberration (attending the large aperture of the pupil called into operation in a bad light) the focussing might be defective. Further experiment has proved that in my own case at any rate much of the effect is attributable to an even simpler cause. I have found that in a nearly dark room I am distinctly short-sighted. With concave spectacles of 36" negative focus my vision is rendered much sharper, and is attended with increased binocular effect. On a dark night small stars are much more evident with the aid of the spectacles than without them.

In a moderately good light I can detect no signs of short-sightedness. In trying to read large print at a distance I succeeded rather better without the glasses than with them. It seems therefore that the effect is not to be regarded as merely an aggravation of permanent short-sightedness by increase of aperture.

The use of spectacles does not however put the small and the large objects on a level of brightness when seen in a bad light, and the outstanding difference may still be plausibly attributed to aberration.

MR. CAETER'S recent paper on "Civilisation and Eyesight" has called up interesting remarks from Lord Rayleigh and Mr

J. R. Capron, but there seems to be a factor yet unconsidered connected with sharpness of eyesight which is not dependent on the varying aperture of the pupil of the eye. The same amount of light exerts different degrees of stimulus on different individuals, and even in the same person the optic nerves are differently affected, according to his health or age. The pathologist is familiar with the exalted irritability induced by inflammation.

The observer of close double stars becomes in time painfully aware that through age his power of appreciating minute points of light is blunted, although his eye may be in a healthy condition, and quite equal to microscopic work under suitable illumination.

The flattening of the cornea, together with the slow reduction of the curves of the crystalline lens, is a common occurrence, and this change is said to commence at the age of forty-five.

Modification of form and the inability to vary the distance between the lens and the retina, due to defective power in the muscles of the iris, are the chief causes of short sight. On the other hand, the eye appears to have great capabilities of modifying itself to circumstances. It may degenerate by disuse, and even become obliterated, as may be seen in the blind aquatic beetles of dark caverns, the flea of the bat, and in many species of underground Aphides. Similarly it would seem that the eyes of the student who habitually pores over half-legible German or other type, or the eyes of the watchmaker or the engraver, who use lenses, will permanently accommodate themselves to the short foci required to view objects at short distances, and such modifications may be conceived to become hereditary.

The pupil of the eye perhaps has an aperture wide enough to admit the pencil of light from any telescope; yet it may be worth some consideration whether the sensitiveness of the eye may not for certain purposes be increased, under due precautions, by the use of some such drug as atropa belladonna. The iris thus might be made less contractile under the overpowering light of a planet, and perhaps allow a better observation of a minute satellite revolving close to its primary. It is a well-recognised fact that a faint star once seen may often afterwards be detected with comparative ease by other persons, if its position be truly shown.

Venus may be often seen in broad daylight, if the planet be pointed to by suitable marks.

Care of course would be taken that the use of belladonna shall not cause the observer to see too much. G. B. BUCKTON

THE controversy in NATURE on this subject has brought back to my thoughts a singular illustration of the power of trained eyesight which seems worth noting, though it does not touch the exact comparison between savage and civilised eyes which is the immediate subject of the letters which have appeared in your columns. I refer to the vastly greater capacity for determining visual direction supplied by the sense of symmetry than by actual discrimination between two slightly distant visible points. If you look at a circle, you can aim at its centre with far greater exactitude than you could aim at a point in the true centre of the figure. Every rifleman and every billiard-player exemplifies this. Suppose a billiard-ball placed a little less than five feet from a pocket, and played at as a half-ball stroke from an equal distance for a winning hazard. This is something like what has to be done from baulk in making a pair-of-breeches stroke into the corner pocket. A fair amateur will pot his ball pretty often; a first-rate professional will do it very often. No one, perhaps, can make it a really safe stroke. But observe the accuracy required. The margin of error allowed on each side of the perfect stroke is, on a severe table, not more than an inch at the pocket. This allows an error on each side of about one degree in the point of impact with a radius of one inch (the ball being two inches in diameter). This one inch subtends at the distance from which the stroke is played (nearly 5 feet), an angle of $1° \times \sin 60°$, $\frac{1}{60}$ = about $8'$. To make the stroke you must first, by eye, place your striking-ball right, then you must, by eye, aim the stroke right, and finally you must make the muscles follow the eye rightly. These three elements of error combined must leave a resultant error of not more than four-fifths of a minute; that is to say, a successful stroke must have a total angular error very considerably less than the smallest angular distance which the eye can appreciate between two visible points. This, of course, explains also the superiority of

Human Hibernation

AS it is obvious that Mr. A. H. Hulk is unacquainted with the facts of what he designates a "well-known Indian and as the matter is one of considerable physiological interest, I think it well to place before your readers the most conclusive evidence which satisfied me of the genuineness of the when I referred to it in the fourth edition of my Physiology," published thirty-two years ago—a reference by the present editor of that treatise. This evidence was obtained by Mr. Braid from Indian sources, and published him in a collected form in 1850, the greater part of which previously appeared in the pages of the *Lancet*. The important feature of it was the testimony of British officers who witnessed the exhumation—most explicit—at least three distinct cases—*to the corpse-like condition of the buried man*, a condition which could not be simulated.

I have since learned from a variety of trustworthy sources similar testimony has been over and over again given by competent witnesses. Moreover, in one of the cases by Mr. Braid, on information supplied to him by a British resident in the summer-house of whose garden was buried, the circumstances of the inhumation and exhumation were such as absolutely to exclude the hypothesis; while in the case narrated by Lieut. A. his "Narrative of a Journey in Rajwarra," 1835, buried in a grave lined with masonry and covered slabs of stone.

It is further worthy of mention that this performance carried on for the sake of gain, but as a religious Many years ago Prof. Max Müller, finding that I was in the matter, kindly placed in my hands a pamphlet India, containing a summary of what is termed Yogi philosophy. The devotees of this system have immemorial been in the habit of artificially inducing more or less complete abstraction, corresponding those of Braidism; and the condition of apathy which the soul is supposed to leave the body in communion with the higher world, is the culmination conditions, only to be reached by the few; and in sequence, a character for the highest sanctity attaches

With the well-authenticated fact of Col. T induction of a state of apparent death, and of recovery from it, as a "leading case," I cannot incredible that such a condition of "dormant vitality prolonged for days, weeks, or even months, in *sphere*. The suspension of the heat-producing course leave the body susceptible of a fatal temperature, if its warmth were abstracted by a much cooler than itself WILLIAM B

An Author's Gratitude

I WISH to express my gratitude to NATURE and to the reviewer in NATURE of my little pamphlet on Electrical Units for exposing a compound error by which the farad came to be described as a fraction of the electrostatic C.G.S. unit of capacity instead of the electro-magnetic unit. Was there ever a greater blunder? It was as if I had said the value of the tenth part of a farthing is sufficient to pay off a million times the National Debt of Great Britain. On recovering from the shock occasioned by the revelation, I hastened to the printer, and got him to correct the error "ere the sun went down," and now I overflow with gratitude to your reviewer, who has relieved me of the awful incubus of an error of the 10^{20} magnitude.
RICHARD WORMELL.

SCIENTIFIC LABORATORIES[1]

I FEEL that the present occasion, upon which you have done me the honour to ask me to preside, is one of very great importance indeed, and I wish some person more competent to preside on such an occasion and give a suitable inaugural address were in my place. I am afraid I must confine myself to something not at all worthy of the greatness of an occasion which is almost the opening of a new university. Not quite so, because the real opening of this college took place several months ago; but still it is an occasion which I feel to be much more than merely the opening of a department—a working department—in the college; an occasion of so great moment that I regret that I shall not be able to give anything that could be properly considered a worthy inaugural address. I shall be obliged to ask your indulgence if I confine myself specially to departments with which I am personally familiar—scientific laboratories. The laboratory of a scientific man is his place of work. The laboratory of the geologist and of the naturalist is the face of this beautiful world. The geologist's laboratory is the mountain, the ravine, and the seashore. The naturalist and the botanist go to foreign lands, to study the wonders of nature, and describe and classify the results of their observations. But they must do more than merely describe, represent, and depict what they have seen. They must bring home the products of their expeditions to their studies, and have recourse to the appliances of the laboratory properly so-called for their thorough and detailed examination. The naturalist in his laboratory with his microscope and appliances for the keenest examination, learns to know more than can be learned by merely looking at external beauties. The geologist brings his specimens to the chemist—is himself a chemist perhaps—brings his crystals to the physical laboratory to be examined as to their physical properties, their hardness, the angles between their faces, their optical qualities. Some people might think this an ignoble way to deal with crystals. But it is not so to the trained eye and deeper thought of the scientific man. The scientific man sees and feels beauty as much as any mere observer—as much as any artist or painter. But he also sees something underlying that beauty; he wishes to learn something of the actions and forces producing those beautiful results. The necessity for study below the surface seems to have been earliest recognised in anatomy, and earliest carried out in human anatomy. I am not going to speak of the work of scientific research generally, but with reference to the special occasion which brings us here this day—the opening of the chemical and physical laboratories of the University College of North Wales. I am going to speak

[1] Address by Prof. Sir William Thomson, F.R.S., on the occasion of the opening of the Laboratories of University College, Bangor.

of laboratories for students, laboratories in which the students work with their own hands. There have been laboratories of investigation from the earliest times. No doubt Aristotle had his; and Archimedes had a laboratory wherever he went—in his bath, even, he observed, and studied, and thought out the laws of hydrostatics. But those were not students' laboratories, and our special subject to-day is a students' laboratory, where they can meet together for the practical study of the various departments of science, where they will be brought together to use their eyes and hands—their eyes otherwise than in merely reading books and looking at pictures or drawings; their eyes to observe accurately, and their hands to experiment, in order to learn more than can be learned by mere observation. To teach students to so work and so learn is the object of a scientific students' laboratory.

The first scientific laboratory that ever existed was that of Frederick II., King of Sicily, and was established between 1200 and 1250. Acting under the advice of his chief physician, Martianus, he made a law that nobody should practise physic or surgery without having studied anatomy practically. He established a school of practical anatomy, to which students flocked from all parts of Europe for many years. Subsequently there was an anatomical school instituted at Bologna; and in those two schools we hear the first of students working in laboratories. The anatomical students' working-room has for several hundred years been generally recognised as an absolute necessity of medical education. But I believe there was no other branch of physical science where students worked in the laboratory until probably twenty years of the present century had passed away. The University of Glasgow is, I think, justly entitled to take some pride in the great modern expansion and extension of the system of giving students practical work in laboratories, as an addition to the education which previously had been confined almost entirely to book-work, or, at best, to attending lectures illustrated by experiments and diagrams. The first chemical laboratory for students, so far as I know, was that founded by a colleague of my own name, though no relation—Thomas Thomson,[1] the great chemist and mineralogist. Prior to 1831 a students' chemical laboratory, under Thomas Thomson, at Glasgow University, flourished and was attended by a large number of students. These were chiefly medical students, but a considerable number also were students who wished to learn chemistry to practise it in the various chemical manufactories in Glasgow and the North of England, while some went to learn chemistry solely for the sake of science. A chemical laboratory has now become indispensable in all universities. A notable development of chemical laboratories with reference to practical education in chemistry, was made by Liebig not many years after 1831. I fix that date from personal recollection. In 1831 I first came to Glasgow, and I well remember that the building containing the chemical lecture room and laboratory existed then. How long before 1831 it was built I do not at this moment recollect. The world-renowned laboratory of Liebig brought together all the young chemists of the day. If I were to name the great men who studied at Giessen I should have to name almost every one of the great chemists of the present day who were young forty years ago. His laboratory was in full and flourishing activity between 1841 and 1845, and continued so for several years more until he migrated to Munich. It is still, I believe, a prosperous institution, carrying out the aims of its founder with undiminished zeal and energy. One of those chemists now living, who was young forty years ago, told me a few days since that Liebig's laboratory looked like an old stable. I believe the building in which we are now assembled was an old stable, but I fail to discover that it looks like an old stable now. If Liebig's laboratory, looking like an old stable, brought out such results to astonish and benefit the world, what must we expect of the beautiful laboratory in which we are now met? What would Liebig not have given for the appliances and advantages afforded by the well-equipped buildings of the North Wales College at Bangor? What would Liebig not have given for the facilities which now exist in these admirably-appointed lecture-rooms in which we are now met, and for the carefully-equipped laboratories and working-rooms, and places for special experimental work covering the area of the old stables and coach-houses of the "Penrhyn Arms Hotel"! If the professors and the students in this College—I think I may already say this thriving College—will be inspired by the zeal of those who have worked before them, a great reward will result even in the first year of the existence of the institution.

With respect to physical laboratories I may be allowed, without being thought egotistical, to say something to which I must speak of my own action. The physical laboratory in the University of Glasgow is, I believe, the first of the physical laboratories of which we have now so many. When I entered upon the professorship of natural philosophy at Glasgow I found apparatus of a very old-fashioned kind. Much of it was more than a hundred years old, little of it less than fifty years old, and most of it was of worm-eaten mahogany. Still with such appliances year after year students of natural philosophy had been brought together and taught. The principles of dynamics and electricity had been well illustrated and well taught: as well taught as lectures and so imperfect apparatus—but apparatus merely of the lecture-illustration kind—could teach. But there was absolutely no provision of any kind for experimental investigation, still less idea, even, for anything like students' practical work. Students' laboratories in physical science were not then thought of. I remember one of the chemists of the Liebig school asking me what was the object of a physical laboratory. I replied that it was to investigate the properties of matter. I could give no better answer now. I may remind you that there is no philosophical division whatever between chemistry and physics. The distinction is that different properties are investigated by different sets of apparatus. The distinction between chemistry and physics must be merely a distinction of detail and of division of labour.

Soon after I entered my present chair in the University of Glasgow in 1845 I had occasion to undertake some investigations of certain electrodynamic qualities of matter, to answer questions which had been suggested by the results of mathematical theory, questions which could only be answered by direct experiment. The labour of observing proved too heavy, much of it could scarcely be carried on without two or more persons working together. I therefore invited students to aid in the work. They willingly accepted the invitation, and lent me most cheerful and valuable help. Soon after, other students, hearing that some of their class-fellows had got experimental work to do

[1] [Note added February 12, 1885:—First Professor of Chemistry in Glasgow University; appointed 1817; held the chair till his death, 1852.

The minutes of the Faculty of Glasgow College show that as early as the first month of 1818, Prof. Thomas Thomson began applying for more commodious premises in which to carry on his work in the department of chemistry. For two years he kept his wants persistently before the Faculty (of which he, being only a "Regius Professor," was not a member) until January 1820, when his efforts were crowned with success. A plot of ground was then purchased at the corner of College Street and Shuttle Street, outside the College precincts, and operations were at once begun, and pushed on with such vigour that the buildings seem to have been finished towards the end of the same year. The building thus erected contained ample and well-designed accommodation for teaching and experimental work. There was a large class-room and a large and conveniently-arranged public laboratory for students, with private rooms for the professor and for the prosecution of experimental research, by the professor and his assistants, or by students and others.

Part of the ground-floor of the premises was let to a tenant (the "Falstaff Tavern" for many years). To-day I found the building still in existence, and occupied by "George Younger and Co.'s Vaults and Stores." Nearly all the rest of the University Buildings within the College precincts have been pulled down within the last twelve years for the "College Railway Station," which now occupies the site of the old Glasgow College and University.—P. G. T.]

came to me and volunteered to assist in the investigation. I could not give them all work in the particular investigation with which I had commenced—"The electric convection of heat"—for want of means and time and possibilities of arrangement, but I did all in my power to find work for them on allied subjects (Electrodynamic Properties of Metals,[1] Moduluses of Elasticity of Metals, Elastic Fatigue, Atmospheric Electricity, &c.) I then had an ordinary class of a hundred students, of whom some attended lectures in natural philosophy two hours a day, and had nothing more to do from morning till night. Those were the palmy days of natural philosophy in the University of Glasgow—the pre-Commissional days. But the majority of the class really had very hard work, and many of them worked after class-hours for self-support. Some were engaged in teaching, some were city-missionaries, intending to go into the Established Church of Scotland or some other religious denomination of Scotland, or some of the denominations of Wales, for I always had many Welsh students. But about five and twenty of the whole number found time to come to me for experimental work several hours every day. In those days, as now, in the Scottish Universities all intending theological students took the "philosophical curriculum"—*suerst collegium logicum*—then moral philosophy, and (generally last) natural philosophy. Three-fourths of my volunteer experimentalists used to be students who entered the theological classes immediately after the completion of the philosophical curriculum. I well remember the surprise of a great German Professor when he heard of this rule and usage: "What! do the theologians learn physics?" I said, "Yes, they all do; and many of them have made capital experiments." I believe they do not find that their theology suffers at all from having learned something of mathematics, and dynamics, and experimental physics before they enter upon it. I had then no other premises than the old lecture-room and the adjoining apparatus room. To meet my requirements for my new volunteer laboratory corps, the "Faculty" (the then governing body of the College) allotted to me an old wine-cellar, part of an old professor's house, the rest of which had been converted into lecture-rooms. This, with the bins swept away, and a water-supply and a sink added, served as physical laboratory (a name then unknown) for several years, till the University Commissioners came and abolished a certain old function of Glasgow University, the "Blackstone Examination." The examination room was left unprotected, its talisman, the old "Blackstone Chair," removed. I instantly annexed it (it was very convenient, adjoining the old wine-cellar and below the apparatus room); and, as soon as it could conveniently be done, obtained the sanction of the Faculty for the annexation. The Blackstone room and the old wine-cellar served well for physical laboratory till 1870, when the University was removed from its old site imbedded in the densest part of the city, to the airy hill-top on which it now stands. In the new University buildings ample and commodious provision was made for experimental work.

In that good old time some students used to come to me under the impression that the laboratory would prove an agreeable lounge, where they could meet pleasantly and spend the forenoon talking matters over. They were soon undeceived as to its being a lounge for idly whiling away time. I hope they were not altogether disappointed when they thought it would be agreeable, and I almost hope they found it even more agreeable than they expected. They certainly learned something of patience and perseverance, if not much science, in the six months of the College session. As a matter of general education for those not going to practise medicine, was it of any use entering a chemical or physical laboratory? I found as many as three-quarters of the students were destined for service in the religious denominations in after-life. I have frequently met some of those old students who had entered upon their profession as ministers, and have found that they always recollected with interest their experimental work at the University. They felt that the time they had spent in making definite and accurate measurements had not been time thrown away, because it educated them into accuracy,—it educated them into perseverance if they required such education. Some students even worked so hard in my laboratory that I had to interpose for the sake of their health. There is one thing I feel strongly in respect to investigation in physical or chemical laboratories—it leaves no room for shady, doubtful distinctions between truth, half-truth, whole falsehood. In the laboratory everything tested or tried is found either true or not true. Every result is *true*. Nothing not proved true is a *result*;—there is no such thing as doubtfulness. The search for absolute and unmistakable truth is promoted by laboratory work in a manner beyond all conception. It is a kind of work in which also patience and perseverance are promoted in a most marked degree. No labour must be shrunk from; everything must be carefully done. There is this which is satisfactory about it: that perseverance is sure to be rewarded. There is no failure in physical science. We do not always find the particular thing looked for; we often find that what we looked for does not exist, or that something else exists very different from what we expected to find; but that something is to be found in any investigation entered upon with intelligence and pursued with perseverance, is a certainty; and also that that something is not valueless follows as a matter of course. Every additional knowledge of the properties of matter is of value.

A large part of the work of a physical or chemical laboratory must be measurement. That might seem rather trying work; "harsh and crabbed" shall we say? Who cares to measure the length of a line in land surveying, or of a piece of cord, or of ribbon, or of cloth? These may not be in themselves essentially interesting occupations; but if it becomes necessary to measure something smaller than can be seen with the eye, the measurement itself becomes an object to inspire the worker with the greatest ardour. Dulness does not exist in science. What do you think of a measurement of something you can only gauge by inference from the performance of the apparatus tested in some peculiarly subtle way? The difficulties to be overcome in physical science in mere measurement are teeming with interest. Properties of matter, or forces to be contended with, oblige us to be always digressing. We cannot go on saying—"We will think of nothing but the object before us." Every person who aims at one object of course perseveres until he attains it; but he keeps his mind open until he can return to some other object never thought of at first, but which thrust itself on him as a difficulty occurring in the pursuit of the first object. The very disappointments in attaining objects sought after in the investigations of physical science are the richest sources of ultimate profit, and present satisfaction and pleasure, notwithstanding the difficulties and disappointments contended with. But I am afraid I am taxing your patience too much. I will only just say with reference to physical laboratories that they are now advancing to something of the method and consistent system that Thomas Thomson and Liebig so greatly gave to chemical laboratories. I, myself, have not done so much as I might have done in that way. The physical laboratory at Glasgow has, I believe, been, more than most others, devoted to whatever work occurred in physical investigation, measuring properties of matter, comparing thermometers, electrometers, galvanometers, and doing other practically useful work. We put the junior students at once into investigations, and let

[1] Results up to 1856 published under this title, as Bakerian Lecture for 1856 (*Trans. R. S.*, and republished recently in vol. ii. of "Collected Papers."—W. T.)

them measure and weigh whatever requires measurement and weighing in the course of the investigation. I look with admiration to what has been done by those who have worked up physical laboratories to their present advanced condition. The physical laboratories of King's College and University College, London, under the admirable organisation and work of Professor Adams and Professor Carey Foster; the Cavendish laboratory at Cambridge, originated by Clerk Maxwell, and admirably systematised and perfected by Lord Rayleigh, have rendered splendid services to physical science all over the world. Much has been done even to provide suitable text-books for use in the systematic practical training of students in laboratory work: for example, the "Treatise on Physical Measurement," by Kohlrausch, which has been for several years a most serviceable manual, and the lately published "Practical Physics" of Glazebrook and Shaw. The physical laboratory system has now become quite universal. No university in the world can now live unless it has a well-equipped laboratory. I hope you will all do your best to make the physical and chemical laboratories of this college a great success; that you will follow example in everything exemplary until the Bangor laboratories become a model to be followed in future laboratories in Wales, England, or any other part of the world. I was not quite accurate when I spoke of this new college in this City of Bangor as *the* University College of North Wales. My friend, Mr. Cadwaladr Davies, your secretary, has reminded me that there was a university of North Wales at Bangor-is-y-coed, in Flintshire—not a city, because it did not combine a bishop and a mayor—but a town which had the honour of having been the seat of the first Welsh university known to history. There may have been universities in Wales before the one which flourished 1200 years ago at Bangor-is-y-coed; but their history is lost in the long night of silence, because no sacred bard sung of their existence. The university of Bangor-is-y-coed had its bard, who tells us that the institution had 2100 students. There you have a worthy object of ambition for the city of Bangor! May it soon have a goodly proportion of the 2100. Perhaps not so long a time may elapse before your college and the other colleges in Wales may reach to such a number. Indeed, I do not see anything unreasonable in hoping and expecting that in a dozen years there will be 2100 university-students in Wales. The population of Wales is more than a million and a half, which is, I think, about a fourth of the population of Scotland; and I do not see why Wales should not have university students in proportion to its population as well as Scotland. I believe the brightness and activity of the Welsh intelligence will thoroughly take up the idea of a university, and profit by it to the utmost, and, I believe, the existence of this institution at Bangor will before twenty years have passed away, be looked upon as having been a great benefit to the Principality. What Wales gained by the university at Bangor-is-y-coed can scarcely now be told, but alas, for that university with its 2000 students, it was destroyed in the year 613 by Ethelfred, King of Northumbria, and its destruction was followed by 900 years of dark ages. Thus we see what the world lost by the annihilation of the first university of North Wales. Another bard, Lewis Glencothy, advocated and sang of the possibility of a university in Wales in the time of Henry VII. Richard Baxter, not a Welshman nor a bard but the great English Puritan divine, reported to the then Government under Cromwell in favour of a university for Wales. Cromwell died before action was taken, and nothing was done in the matter for nearly 200 years, when a very active desire sprang up and active co-operation among all parties was entered upon, for having a university established in Wales. We see everything now prospering in that direction. I look forward hopefully to the time when this college of Bangor—not an independent university of its own—will be a college of the University of Wales. All the colleges of Wales, equipped to do the work of a university, might be united to form a University of Wales. There are very many important advantages in favour of such an arrangement. No doubt it is an object of honourable ambition; but it may be asked if a college does all the work of a university, who does it matter whether it is called a university or not? It is of considerable importance that your college should be either a university itself, or part of a university of which it is an integral college. One of the advantages would be that the teaching of the college would be enabled to take a more practical form than it can possibly take as long as its main purpose is that of preparing students for the degree examinations of London University. The degree system of London University fills a widespread want—a want felt over the whole range of the British empire—a want of marking by the stamp of a university degree, if not by some more suitable title, the possession of knowledge and of a certain amount of training by those who have not had the opportunity of obtaining that knowledge in any thoroughly equipped college or university. That is a splendid reason for the existence of the London University, and it has well fulfilled its reason for existence. But, for all that, it would be greatly better for the students of the University College of North Wales if the teaching were conducted with reference to an examination carried on by their own professors and colleague professors in other properly equipped Welsh colleges. It is the greatest mistake in respect to teaching and examining to think that the examiner is an inspector. An examiner of schools must to some extent take that position. But in university work teaching and examining must go side by side, hand in hand, day by day, week by week together, if the work is to be well done. The object of a university is teaching, not testing. Testing products comes at some times, and for some special purposes, to be a necessity; but in respect to the teaching of a university, the object of examination is to promote the teaching. The examination should be, in the first place, daily. No professor should meet his class without talking to them. He should talk to them and they to him. The French call a lecture a *conférence*, and I admire the idea involved in that name. Every lecture should be a conference of teacher and students. It is the true ideal of a professorial lecture. I have found that many students are afflicted when they come up to college with the disease called "aphasia." They will not answer when questioned, even when the very words of the answer are put in their mouths, or when the answer is simply "yes" or "no." That disease wears off in a few weeks, but the great cure for it is in repeated and careful and very free interchange of question and answer between teacher and student. Professors and students must speak to one another. One of the greatest things is to promote freedom of conversation in such classes, to cultivate in them the power of expressing ideas in words. Then something more definite than *viva voce* examination can come. Written examinations are very important, as training the student to express with clearness and accuracy the knowledge he has gained, and to work out problems, or numerical results; but they should be once a week to be beneficial. If occurring once in two or three months they will lose their effect in promoting good teaching, and can be no more than a test; if only once a year they are mere inspector's work. The object of the university should be teaching, and examining should only be part of its work, and that only so far as it promotes teaching. The success of the University should depend on good teaching, and the candidate should be granted a degree who does not show that he has taken advantage of the good teaching. But it is impossible to carry out that programme to best advantage by a college which is not in itself an integral part of a university. Such examinations as those of the London University are necessarily arranged to suit thousands of candidates who have learned in different schools, and

s contain questions that would be most suit- particular mode of teaching. The kind of would be of a different nature if the giving ions devolved upon those who had in hand

Those who have the teaching can give an vastly more useful one that would re-act ng in a way that an examination of a multi- nts trained at all kinds of institutions, and by private reading, could not possibly do. seems to be a matter of high importance here should be a University of Wales; that onsider it to be a great object to be attained, er—but the sooner the better—the establish- University of Wales, with the University Col- Wales an integral part of it. I have much ishing the University College of North Wales , and I trust that the laboratories now opened f great value in promoting and aiding the ice.

I.YNOMIALS IN ZOOLOGY[1]

days of Linnæus scientific zoologists have lly adopted the binomial system of nomen- was invented and introduced by that great o long as the idea of the fixity of species, as ated entities, prevailed, there was no excuse from the Linnean plan. Such an idea as a ries between two species, or the division of two or more local forms, was hardly under- older authors. But of late years, since the tance of the derivative origin of species, it universally acknowledged that sub-species al forms do exist in Nature, and many and have been proposed for indicating them. hat is, the usage of three names, of which it of the sub-species—are in great favour section of American zoologists, and there said in their defence. But the concession , it is said, would in some cases not be suf- rinomials and Polynomials must necessarily render nomenclature inconveniently long. n, the well-known herpetologist of the Com- um of Zoology at Harvard College, Cam- , in the pamphlet now before us, to the t there is no other or better method than

Mr. Garman proposes to designate the s or sub-species of a species by symbols 3), (C), (D). Supposing that the (C) form sist of several sub-varieties he would name b), (C.c). Still further subdivisions might s forms (C^{a1}), (C^{a2}), (C^{a3}), and (C^{a4}), (C^{a5}), polynomial "*Amblystoma tigrinum mavortii suspectum maculatissimum*" would be ($C.^{a5}$) *Amblystoma tigrinum*," the "advan- for general literature is "apparent"! TEMPERED GLASS

y pleased to be able to chronicle an appli- which Mr. Frederick Siemens has recently generative gas radiating furnace, described of last year (NATURE, vol. xxxi. p. 7). the production of glass which appears to nogeneous character and of considerable ardness, and will doubtless become avail- mber of useful purposes. The scientific is applied in the three distinct processes propose to refer shortly, is that of keeping the whole body of the glass at a uniform temperature during the operations of heating and cooling—that is to say, that at each unit of time the whole mass shall be at one temperature. Two methods have hitherto been employed by means of which glass has been rendered more or less independent of variation of temperature. The oldest of these is that carried on in the annealing kiln, in which the manufactured articles of glass are allowed to cool very slowly. The more modern is that of De la Bastie; in this process the finished articles of glass had generally to be annealed in the first instance, then heated to such a temperature as to soften them, when they were immersed in a bath of heated oil maintained at a temperature above 300° C., which was said to make them tough. The objection to annealing is mainly that of cost, but the objection to the De la Bastie process is that it is wrong in principle, as, owing to the manner in which cooling is effected, the glass is in a state of tension throughout, which is brought to evidence by means of the polariscope. The glass produced by the processes to be described are almost free from internal strain, and Mr. Siemens holds that, could the principle he propounds be carried out perfectly in practice, the glass would be free from tension throughout its whole mass. A corollary which may apparently be drawn from this proposition is that every metal not cooled in the way proposed is in strain; but that, owing to the much greater tensile strength of metals, the state of tension does not become evident in the same manner as in glass, which is notably brittle.

Press-hardened Glass.—Only glass of the very best quality is suitable for hardening. It is cut into the proposed shapes and placed in the radiation furnace until soft; it is then removed and placed between cold metal plates, and cooled down in the proportion of its volume or capacity for heat. Glass may be cooled so rapidly by this means that the diamond will not touch it; the process is mostly applied to sheet and plate glass, which may either be plain or decorated, and whose strength is thereby increased eight times. The degree of hardening which may be attained depends on the temperature to which the glass is heated and the rate at which it is cooled. The higher the temperature, and the more quickly the glass is cooled, the harder is the glass. Thus, for very quick cooling copper plates are used in the presses, and the glass is rendered exceedingly hard; when a less degree of hardness is desired, iron plates, or even these covered with asbestos, or clay slabs, may be employed.

Sheet glass of ordinary thickness is heated in a minute and cooled in half a minute. It is remarkable that this can be effected in so short a space of time without injury to the glass, and is due to the uniformity of the heating and cooling operations. Owing to the high temperature at which this process is carried on, more refractory enamels, such as those used for porcelain, can be applied, and the enamel is thus rendered as indestructible as the glass itself.

Semi-hardening is employed for goods to which presses cannot be easily applied. The glass is heated up to a high temperature, but not to such a degree as to affect its shape, and is then placed within an iron casing having internal projecting ribs so arranged as to hold the glass article in position and to touch it at the fewest possible points. The casing with its inclosure is cooled in the open air. The process is only applicable to articles of nearly uniform thickness throughout; it increases the strength of the glass about three times, and renders it less liable to be effected by changes of temperature than ordinary glass is.

The third kind of glass, which is known as *hard-cast glass*, has not yet been introduced commercially, but samples of the work produced in the form of sleepers, tramway-rails, grindstones, and floor-plates were exhibited at the meeting. The method of production is very simple.

[1] "Polynomials and Names in Zoology." By S. Garman, U.S.A. From the *Proceedings* of the Boston Society of Nat. Hist. 1884.

Glass made in a continuous glass-melting furnace is run into moulds as with iron castings. The only precaution that has to be taken is that the moulding material shall have as nearly as may be the same specific heat and the same conductivity for heat as glass. Various mixtures of materials that are easily obtainable and not costly are suitable, such as mixtures of powdered porcelain, glass pots, metal turnings and filings, and such minerals as heavy spar and magnetic iron ore. These are pulverised and mixed in certain proportions, and then moulded in the ordinary way. The glass being run into the mould, the mould and its contents are heated up together, and then cooled together, and, when cool, the mould is opened and the glass removed. Glass may thus be cast into forms which it would be impossible to produce otherwise. That glass may thus be manufactured of great homogeneity was proved by the clear ring of a large tuning-fork made of the material, and in the manner described. Mr. Siemens promises on a future occasion to bring this matter again before the Society of Arts, after the completion of the works which he is now erecting for the manufacture of glass according to the process last described. As regards the other processes, the manufacture has increased in six years from 600*l.* to 7000*l.*, and, considering the very cheap rate at which hard glass castings can be produced—viz. about 5*s.* 6*d.* a hundredweight—Mr. Siemens feels satisfied that a large business will be done, more particularly as they supply a want which is felt on all sides; and thinks that glass not being liable to oxidation, as soon as it could be depended upon as regards strength, it would be applied for purposes for which metals, stone, and porcelain have hitherto been used.

THE PHYSIOLOGICAL LABORATORY AND OXFORD MEDICAL TEACHING

[WE regret to learn that another attempt is being made to suppress physiological teaching at Oxford. The not-over-scrupulous foes of scientific teaching and research have, we understand, distributed manifestoes by thousands all over the country. We hope, therefore, that the following statement will receive equally wide circulation. Scarcely any of the well-known men who have signed the statement are in any way connected with what is generally known as science; certainly not one of them would have signed it had there been the least suspicion that in the Oxford Laboratory there would be any approach to cruelty:—]

A decree to provide for the expenditure of the department of Physiology will be submitted to Convocation on Tuesday, March 10. The annual sum required for this purpose is 300*l.*, besides 200*l.* for the salary of the Demonstrator of Histology.

The arrangements for the organisation of a complete system of instruction in the subjects of the first B.M. Examination and of the first and second Professional Examinations of the Conjoint Board of the College of Physicians and of the College of Surgeons in London are in progress, and will soon be completed. The new Lecturer on Human Anatomy will very shortly be appointed, and the Physiological Laboratory will be completed and ready for occupation by the end of the summer; so that before next October the University will be in a position to undertake the teaching of Human Anatomy and Physiology. The arrangements for teaching the other subjects in which instruction is required by medical students are also in progress.

As, in accordance with the recent resolution of the Colleges of Physicians and Surgeons, Candidates who have satisfied the Oxford Examiners in Anatomy, Physiology, and the other subjects of the first and second Professional Examinations, will be exempted from further examination in these subjects, Members of the University will in future be able to complete their first two years of medical study without leaving Oxford.

The purpose for which the expenditure is required is instruction not research, and no experiments upon the living animal involving pain will be used for demonstration to students or instruction, with or without anæsthetics.

It is, however, intended by those who desire absolutely to prohibit such experiments in physiological inquiry, to oppose the decree for the maintenance of the laboratory. Energetic measures are being taken to this end. The rejection of the decree would involve fatal consequences as regards the above-mentioned scheme for the teaching of medical science. The University has already twice pronounced upon the issues now sought to be raised, by votes taken in unusually full Convocations on June 3, 1883, and February 5, 1884. We, therefore, trust that you will be good enough to attend and vote in favour of the Decree on March 10, at 2 p.m.

H. G. LIDDELL, Dean of Christ Church.
J. FRANCE BRIGHT, Master of University.
GEORGE C. BRODRICK, Warden of Merton.
J. P. LIGHTFOOT, Rector of Exeter College.
DAVID B. MONRO, Provost of Oriel.
JOHN R. MAGRATH, Provost of Queen's.
J. E. SEWELL, Warden of New College.
W. W. MERRY, Rector of Lincoln.
W. R. ANSON, Warden of All Souls.
E. H. CRADOCK, Principal of B.N.C.
T. FOWLER, President of Corpus.
J. PERCIVAL, President of Trinity.
H. D. HARPER, Principal of Jesus College.
G. E. THORLEY, Warden of Wadham.
EDWARD S. TALBOT, Warden of Keble.
WILLIAM INCE, Regius Professor of Divinity.
H. W. ACLAND, Regius Professor of Medicine.
W. H. FREEMANTLE, Fellow of Balliol College.
JOHN CONBOY, Christ Church.
ALFRED ROBINSON, Fellow of New College.
T. HERBERT WARREN, Fellow of Magdalene College.
F. MAX MÜLLER, Corpus Professor of Comparative Philology.
BARTHOLOMEW PRICE, Sedleian Professor of Natural Philosophy.
HENRY NETTLESHIP, Corpus Professor of Latin.
JAMES LEGGE, Professor of Chinese.
J. EARLE, Professor of Anglo-Saxon.
JOHN RHYS, Professor of Celtic.
T. H. T. HOPKINS, Fellow of Magdalen.
W. LOCK, Fellow of Magdalen College, Sub-Warden of Keble College.
W. W. JACKSON, Fellow of Exeter, Censor of Non-Collegiate Students.
H. F. TOZER, Fellow and Tutor of Exeter.
A. G. BUTLER, Fellow and Tutor of Oriel.
AUBREY MOORE, Tutor of Keble and Magdalen.
ROBERT L. OTTLEY, Student of Christ Church.
W. MARRIOTT, Reader in Indian Law, Fellow and Tutor of Balliol College, and Fellow of All Souls' College.
H. F. PELHAM, Exeter College.

THE MAXIM GUN

MR. HIRAM STEVENS MAXIM, the well-known American engineer, has lately brought out a new form of a machine-gun, which is attracting a great deal of attention in military and naval circles. This gun is a completely new departure. It takes the cartridges out of the box in which they were originally packed, puts them into the barrel, fires them, and expels the empty cartridges, using, for this purpose, energy derived from the recoil of the barrel. Of course it is necessary to put the first cartridge into the barrel by hand. When, however, this is done, and the trigger pulled, the gun will go on and fire as long as there are any cartridges in the box

ticular cartridge depends upon its own power to withdraw itself from the barrel, it will be obvious that the cartridge cannot remove itself from the barrel before it explodes.

A gun which loads and fires itself is certainly a novelty, and presents many interesting features and possibilities to any one who takes an interest in implements of warfare.

The gun may be trained in any direction by turning the crank which operates a tangent screw, the stem of which projects from the platform immediately below the cartridge box seen on the top of the tripod, whilst a fine adjustment in elevating may be obtained by turning the small hand wheel, which forms a part of the diagonal telescopic brace which supports the rear of the gun. By loosening the three-handled screw immediately below the central standard, the gun may be turned completely round, and by loosening the thumb screw of the telescopic brace, the gun is absolutely free to be moved up or down or in any direction while firing. If, however, it is desired to have a definite stop to the horizontal play of the gun, as, for instance, when firing upon a bridge, a pass, or a ford, or upon earthworks, the gun may be sighted between the two points, and adjusted by the thumb nuts on the tangent screw stem, when the gun will be free to operate between these two points, but will not go beyond them. Fig. 1 is a perspective view of the gun. Fig. 2 is a longitudinal central section of the weapon. A is the block or bolt which slides freely after the manner of the cross head of a steam-engine; B is the barrel; C the locking device for securing the block to the barrel at the instance of discharge; D is the cocking lever; E, the carrier which draws the cartridges out of the belt and deposits them in the feed wheel G; F is the belt wheel which draws the belt of cartridges into the gun; H is a connecting rod made slightly elastic by being provided with a strong spring; I is a crank which does not, however, turn completely round; L is a point of resistance, against which the cocking-lever, D, strikes at each rearward motion of the block; K is a shaft connected with the trigger, which operates upon the sear and also upon the controlling chamber J; M is the extractor which starts the cartridge from the barrel; N is a bar which holds the locking device C in position, and which raises it or unlocks it at each rearward motion of the barrel; O is a casing surrounding the barrel, which may be used, if desired, as a water jacket.

RORAIMA

OUR readers will be interested in reading the following letter, which has just been received at Kew, from Mr. im Thurn, in confirmation of his telegram already published (NATURE, vol. xxxi. p. 342), announcing his successful ascent of Roraima:—

Georgetown, February 4, 1885

I have just sent a most brief telegram (such things are expensive here) which will, I hope, give the first news that Roraima has been ascended; and I much wish I could write even a brief report to go by this mail, but ever since I have been back (we got back four days ago) I have been in bed with the most severe attack of fever and ague that ever befel me, and, though the doctor assures me that I have now turned the corner, I am so weak as to be quite unable to sit up. However, before next mail I must manage something. And in the meantime I send a local paper which purports to give an account of the expedition derived from myself. The main facts are tolerably correct, but the details are much blurred.

We were quite successful in getting to the top, and have found that the plateau is by no means the isolated spot it has sometimes been supposed to be. It was, however, a great disappointment that, our way up being so extremely laborious, it would be quite impossible, without a very large expenditure in somewhat smoothing the path, to carry up hammocks, &c., provisions, and firewood (for there are no trees on the top and it is bitterly cold)—it was a great disappointment, I say, that we could only explore the top for a short distance from the point which we first reached. I see, however, no reason to believe but that the whole top is of one character. The scenery is in the highest degree wonderful. I made many fairly successful sketches (considering I am no artist), which will give a very fair idea of the mountain and of the scenery on the top. As I wish to keep the original sketches for the present, to copy them at my leisure, I have just handed the half-dozen most characteristic amongst them to a photographer here, who has before been fairly successful in copying drawings for me, and I hope to send you copies by next mail. The vegetation (on the top) is most wonderful, but somewhat scanty and quite dwarf. I have between 300 and 400 species for you. I have also some living plants (*Heliamphora*, three most exquisite Utricularias, two of which are, I fancy, new; and a few other things), but, as these want much nursing, I have put them into wardian cases, and shall take them home for the present. (I miss Jenman now and have throughout the expedition, immensely.)

Yours very truly,

(Signed) EVERARD F. IM THURN

NOTES

AT the moment of going to press we have received from Sir E. J. Reed a communication protesting against some of the statements made in our article last week on "The Relative Efficiency of War-Ships," and pointing out that the system of construction advocated by him was greatly modified during the ships' progress. So far from wishing to deal unfairly with Sir E. J. Reed's views, one of our chief objects was to support his protest against the existing state of things, by suggesting that scientific experiments should be resorted to to settle some of the questions on which doubts have been expressed by contending authorities.

WE regret to learn that M. Milne-Edwards is lying in a precarious condition.

OUR readers will regret to learn that Prof. Bonney will resign his post as secretary of the British Association after the Aberdeen meeting. Prof. Bonney, we believe, feels compelled to take this step mainly on account of the inroads which the work of the Association makes upon his time. No one will regret his retirement more than the council and his fellow officials.

M. BOUQUET DE LA GRYE has received a mission from the French Minister of Public Instruction to proceed to Teneriffe in order to study the variations of gravitation according to altitude.

WE have received from the Royal Society of Public Medicine of Belgium its recent monthly tables. With the present year it assumes a new field of usefulness. Founded originally in 1862, it was composed of men who by their position or special knowledge were able to participate (1) in determining the causes of mortality in general, and the circumstances which affect public health; (2) in informing and assisting the authorities by special studies and researches; (3) in preparing the medical topography of Belgium; and (4) in discussing at annual public meetings questions presently relating to this work. The Society is formed of eleven local subdivisions, each sending a number of members to form the general council. But in addition to these local divisions, for administrative purposes, the Society is also divided for the scientific service into a number of zones limited according to the physical nature of the districts. The medical topography of the kingdom, and all questions relating to it, are studied according to these zones. During last year the Society has

quiry into the sanitary situation of the country, ghly approved of at the Health Exhibition in now it has been determined to continue the inves- systematic and permanent basis. The members of ittered over Belgium are called on to assist in the ng, and the specimen forms which they are required ily are now before us. There are thirteen zones, ig subdivided into districts. The physicians who f the Society, or who are willing to participate in e requested to state the diseases of which patients ice have died during the month. From these a general statement, and tables of relative statistics the central body. In course of time a medical the country, the enormous public advantages of arent, will be issued.

ctions of the Seismological Society of Japan for part 2) contains a paper, by Prof. Milne, on 387 served during two years in North Japan. To extent of country over which an earthquake was buted bundles of post-cards to the Government mportant towns within a distance of 100 miles of request that every week one of the cards should h a note of any earthquakes that might have this expedient it was discovered that the Hakme the south of the Tokio plain appeared to stop ming from the north, and accordingly the barrier vas stopped in that direction, but was extended e north until it included the forty-five principal ain island to the north of Tokio, besides several

In Tokio, observations as to direction, velocity, ere made with various earthquake instruments. of the principal instruments used, with a com- relative merits, has already been given by Prof. c. of the *Transactions* of the Society. The second er is devoted to a list of the 387 earthquakes, particulars of each; 124 maps of earthquake dis- as numerous other illustrations, are appended. n exhaustive study of these earthquakes may be follows:—(1) As to distribution in space: of the 4 were local, that is, they were not felt over an an 50 square miles; 198 of these were confined , and 56 were inland. The average diameter of e over which the remaining 133 extended was but four or five of them embraced a land area square miles. These great shocks originated nd consequently were not so alarming in their any which originated nearer to or beneath the ltaneous shocks: some of the disturbances took remote from each other, whilst intermediate record them. (3) Origins of earthquakes: the under this head is that the greater number of t in Northern Japan originated beneath the cent. of the whole having so originated. The most shaken is the flat alluvial plain around , the large number of earthquakes felt in low ared with the small number felt in the mountains ole. It is also noticeable that in the immediate e or recent volcanoes seismic activity has been p marking the general distribution of volcanoes of the greatest seismic activity shows that these related to each other. The district, too, where the most numerous, is one of recent and rapid slopes down steeply beneath an ocean which, n the coast, has a depth of about 2000 fathoms, er side of the country, where earthquakes are ire, at the same distance from the shore the ut 120 fathoms. In these respects the seismic regions of Japan resemble those of South America, where the earthquakes also originate beneath a deep ocean, at the foot of a steep slope, on the upper parts of which there are numerous volcanic vents, whilst on the side of this ridge opposite to the ocean earthquakes are rare. (4) Relation of earthquakes to various natural phenomena: the preponderance of shocks in winter, as revealed by this investigation, is really remarkable; 278 took place in the winter months, as against 109 in the summer, and of the former number, 195, or more than half of the whole number for the two years, took place in the three coldest months of the year—viz. January, February, and March, in other words, there is a general coincidence between the maximum of earthquakes and the minimum of temperatures. But the relation of seismic *intensity* (as distinct from the number of earthquakes) is even more remarkable, for the figures show that the winter intensity is nearly three and a half times as great as the summer intensity. M. Perrey thought he discovered a maximum of earthquakes for the moon's perigee, but no such maximum has been found for Japan. Speaking generally, no marked coincidence was found in the present instance in the occurrence of earthquakes and the phases of the moon. The above are the general results, stated briefly, of the most exhaustive and remarkable study yet undertaken in the domain of seismology.

La Nature contains a long report on the Andalusian earthquakes, from the pen of M. Noguès, a mining engineer of Granada, which, as being the first scientific investigation of the catastrophe, is worthy of special notice. The whole movement presented three phases. The first manifested itself, prior to December 25, at Pontevedra, Vigo, and in Portugal; in other words, in the eastern part of the Iberian peninsula. The second was very short and intense, and made itself felt in the centre and south; it reached its maximum intensity on the night of December 25. The third phase lasts still in the provinces of Granada and Malaga, and extended east to Valencia. The oscillatory movement of December 25 embraced a considerable superficial extent. The disturbed area in the peninsula is comprised between Cadiz and Cape Gaeta, between Malaga and the Carpetena chain. The movement became more and more intense as it left this mountainous mass and travelled in a southerly direction, until it attained its maximum in the region between the Serrania de Ronda and the Sierra Nevada of Granada. The oscillatory motion was gradually accentuated towards the south, especially on the southern side of the great central Spanish plateau, bounded by the slope of the valley of the Guadalquivir (Seville, Cordova, Malaga, and Granada). M. García Alvarez localises the phenomenon in Andalusia, and regards the Sierra Nevada as the point of departure. M. Noguès then deals in succession with the relations between the seismic motions and the geological structure of the district, the geological phenomena, such as fissures in the earth, produced by the earthquakes, and alterations caused by them in the level of springs. He sums up his conclusions by pointing out that the geological observations which have been made so far, although local, limited, and imperfect, demonstrate that there were two different kinds of motions—one oscillatory, the other a trembling movement. Every one who felt the great earthquake of the 25th experienced first a vertical shock, and then, after a short interval, another movement like a balancing. A great fissure at the village of Guevejar presents at two points two interesting sections. At one the trunk of an olive-tree has been split in two from its root to the branches, as if from a blow of a hatchet, each part occupying a side of the fissure, one on one side, the other on the other. At another part the fissure has divided in two the wall supporting the wheel of the powder-factory at Guevejar. The cracks in the houses in the village are in lines parallel to these fissures, and the marks left in the soil

indicate an oscillatory motion. The chimneys, in many cases, were turned half around on their axes, without any further disturbance of a single portion of the structure; and, in fact, an examination of the various marks left by the earthquake of December 25 places it beyond doubt that there was a trembling as well as an oscillatory movement.

On Wednesday evening last week, at half-past eight, three heavy shocks of earthquake, lasting for two seconds, and passing from west to east, were felt at Temesvar, in Southern Hungary. On Thursday morning there was another and slighter shock. Two sharp shocks were felt on Friday in Spain, most severely in Granada, Loja, Alhama, and other districts on both sides of the Sierra Tejea. In the Provinces of Granada and Malaga many houses were damaged, and buildings that had suffered in the previous earthquake were now knocked down.

The last number of the *Bulletin* of the Essex Institute (Salem, July to December, 1884) is of especial interest, as it contains the proceedings held in commemoration of the fiftieth anniversary of the foundation of the Essex County Natural History Society, of which the Institute is the natural heir and successor. The papers which were read were all appropriate to the occasion. Prof. Morse dealt with the condition of zoology fifty years ago and now, in connection with the growth of the Institute. Mr. Robinson discussed the progress of botany in Essex county during the half-century, and the influence of the Society on it, dividing his paper into three parts: (1) The condition of botanical knowledge now as compared with fifty years ago; (2) the progress made in that period in the district, as shown by the increase of libraries, public museums, private herbaria, &c.; and (3) the practical benefit and general knowledge bestowed upon the people of the county by such increased accurate knowledge of the subject and the facilities for obtaining it. It would be impossible to sum up more clearly and thoroughly, from all points of view, the benefits of such societies as the Essex Institute to their localities and to the progress of science in general than is done in this paper. Mr. McDaniel deals with geology and mineralogy, in which the work has not been so great as in botany, zoology, and prehistoric archæology, "owing to the bent and profession of the leading members." The commemoration papers conclude with a brief historical sketch by Mr. Samuel Fowler, who notices as evidence of the liberality of the founders of the Society that, though nothing was heard of women's rights fifty years ago, they invited ladies to join them, adding in their circular: "It is anticipated that they will contribute much to the success of the Society." The historiographer is able to add that these anticipations were realised, for "ladies have always taken a deep interest in the Society and its work, and have greatly aided us in many ways." The result of this "stock-taking" after half a century is a legitimate source of pride to the inhabitants of the good old town of Salem and its neighbourhood.

It will interest many of our readers to know that an Exhibition of Photographs by Amateurs will be held at 103, New Bond Street, from April 23 to May 9, under the auspices of the "London Stereoscopic Company." This, as far as we know, will be the first of its kind, and will doubtless be patronised by a large number of exhibitors, and tend to encourage the growing popularity of photography amongst amateurs. Several photographs by the late Mr. Cameron, of the *Standard*, will form an interesting feature of the Exhibition. Prizes to the value of 200*l.* will be awarded. Intending exhibitors are requested to communicate with Mr. T. C. Hepworth, at 108, Regent Street, W.

The popular Chinese practice and superstition with regard to persons in an epileptic fit are not a little curious. When a person gets an attack of epilepsy, those about him rush away the a few blades of grass, which they put into his mouth. They believe that during an attack of epilepsy the spirit leaves the body, and, there being a vacancy within, it is immediately filled by the spirit of an animal, generally a sheep or a pig, and the sound in the person's throat as he begins to revive is taken for the bleating of the one or the grunting of the other. Under these circumstances they attempt to propitiate the animal by putting grass into the man's mouth, possibly under the impression that they can entice the animal's spirit in the man to remain till his own returns; and on no consideration will they remove him till the fit is over, for, if they did, they believe his own spirit would not be able to find him again, and thus he would die.

Messrs. W. Swan Sonnenschein & Co. will shortly publish a translation, by Prof. Hillhouse, M.A., of the Mason Science College, of Strasburger's "Das kleine botanische Practicum."

The next Ordinary General Meeting of the Institution of Mechanical Engineers will be held on Friday, March 20, at 25, Great George Street, Westminster. The chair will be taken at 7.30 p.m. by the President, Mr. Jeremiah Head. The following papers will be read and discussed, as far as time will admit:—On recent improvements in wood-cutting machinery, by Mr. George Richards, of Manchester (adjourned discussion); description of the tower spherical engine, by Mr. R. Hammerton Heeman, of Manchester; on the history of paddle-wheel steam navigation, by Mr. Henry Sandham, of London.

The Annual Report of the Belfast Naturalists' Field Club is a respectable volume of about 260 pages, with twenty-four plates containing about fifty illustrations, devoted in the present number wholly to cromlechs and other prehistoric remains in the north and west of Ireland. The Society has attained its majority (the past year being its twenty-first), and the secretary is able to report that it was never more prosperous either as regards increased membership, financial condition, or the value of the work done. Among the papers read during the winter session we notice: on the antiquities of the West of Ireland, on a microscopical examination of a bit of ground from Magilligan strand after a storm (in which Canon Grainger describes the castaways after a gale), ants, a trip to America, the age of the basalts of the North-East Atlantic (by Mr. J. Stirling Gardner), while the appendix contains three longer papers: Notes on Irish coleoptera, by Messrs. Halliday and Stewart; the cromlechs of Antrim and Down, by Mr. Gray; and notes on prehistoric monuments at Carrowmore, near Sligo, by Mr. Elcock. It is to the two last that the numerous illustrations are attached.

M. Waldemar Czerniawsky, already known for his work on the fauna of the Black Sea, has now published at Kharkoff a work on the "Cristacea decapoda Pontica littoralia," accompanied by several plates, being a very elaborate description of the Black Sea Decapods. The number of Pontic species of Decapods has been increased by twenty, reaching thus to eight species, with numerous varieties, though it will probably be greater when the depths of the Black Sea have been better explored. The results of this work are numerous and interesting. The species offer altogether a very great variety of forms. The Black Sea contains the local forms of Mediterranean varieties, while in the Celtic region are found the local forms of the varieties. The author asserts that the metamorphosis of the superior crabs, such as *Carcinus*, which presents nine different stages, are a repetition of their genealogy, and arrives at a series of very interesting conclusions as to the genealogy of different species. All three species of *Astacus* which are found in the Ponto-Caspian fauna are maritime forms which have remained

er, and even the *Acicula polyphylla*, Rathke, o-lake Abrau, is a remainder of a maritime *Thelphusa*, which has gigantic representatives spian. Certain crabs reach really gigantic size spian region; such as *Eriphia spinifrons* and on the shores of Crimea and at Odessa. While a great development only in very salt and warm ich the same size under the influence of reverse e Decapods of the Azov Sea have not yet been descriptions of the species and their varieties atio, as also the explanations to the plates, the d accessible to all zoologists, many of whom, gret not to be able to understand the notes graphical, and sometimes adding minor details n), which are in Russian.

ved from the Johns Hopkins University the two es on Historical and Political Science. One aws in mining districts, and describes the regu e of land made by agreement among the miners ie Western States. They show a return to where use is made the proof of ownership, and se of the various lots is of prime importance. author of this number. The second, by the rs, describes the influence of the State of Mary- d cessions of the United States, and is specially references to Washington's project for devoting to him by his native State, Virginia, to the National University.

eption of a few pages, the whole of the last No. 4) of the *Boletin de la Academia Nacional* rdova (Argentine Republic) is occupied by a r Doering on meteorological observations made a during 1883. There were a continuation of im in 1882 on evaporation, and the various x different depths. But for 1883 he has added and arranged the tables as follows:—Atmo- emperature of the air, the elastic force of the sr, relative humidity, evaporation in the shade mperature of the soil, solar radiation, storms, ere is also a short paper on the observations of lition to Bahia Blanca, to observe the transit

to the Zoological Society's Gardens during the e two Wood Hares (*Lepus sylvaticus*) from presented by Mr. F. J. Thompson; an Alex- t (*Psittacula alexandri* ♀) from India, pre- /. Hay; a Common Magpie (*Pica rustica*), by Mr. H. Clare; a Slowworm (*Anguis* presented by Mr. R. Gunter; a Short-tailed *turus brachyurus*) from Western Australia, Brown Pelicans (*Pelecanus fuscus*) from the based; an Isabelline Lynx (*Felis isabellina* ♀) ved in exchange, two Spotted Ichneumons *ta*) from Assam, received on approval.

ASTRONOMICAL COLUMN

17.—In a note to the Royal Society (*Phil.* Halley reported that on Monday, June 16, ng, the sky being very serene and calm, he amining Mars, then very near the earth, to in his 20-foot telescope he could distinguish seen upon his disk, and directing his tele- ose he accidentally met with a small whitish e planet, which seemed to emit from its upper f radiation, directed nearly towards the point The great light of the moon, then not far e at hand, hindered the object from being distinctly seen, but he determined its place to be nearly in 17° 12′ of Sagittarius with 4° 12′ south latitude. The position, he adds, would be more exactly found by means of two small stars near it, the more northerly of which had the same latitude and followed at the distance of about six minutes; the other was about four minutes south of the former, and followed it about a minute, "the angle at the northern star was somewhat obtuse, of about 100 degrees, and the distance of the nebula from it was *se* quialteral to the distance of the two stars, or rather a little more." No motion being detected in over one hour, Halley doubted if it were a comet, but on June 15, the moon being down and the sky clear, he had a distinct view of the two stars, but there was no sign of the nebulosity where it had been observed on June 10. He was led by this circumstance to remark upon the number of comets which might escape notice, from their being telescopic objects, and adds that, although comets had been seen elsewhere in 1698, 1699, 1702, and 1707, he could not learn that any comet had been perceived in this country for the thirty-five years previous to the observation above described, which implies that none had been seen here since the year 1682, that of the appearance of the famous comet which bears Halley's name.

The small stars to which Halley refers would appear to be Nos. 16,627 and 16,631 in Oeltzen's Argelander.

THE VARIABLE STAR S CANCRI.—A minimum of this short-period variable being due during the night of February 20, Mr. Knott availed himself of a fine sky at Cuckfield to observe it as long as it was possible to do so. The watch commenced at 8h. 40m., and ended at 17h. 15m. At 9h. 23m. no change was noticeable, but soon after 9h. 30m. the star began to decline, and gradually fell from 8·1 to 10·4 mag., which point was reached about 15h. 30m. From that time till 17h. 15m. no certain change was detected, though at 17h. 15m. there was a suspicion of the star being possibly a trifle brighter. By this time it was 17h. past the meridian, and getting too low for observation. As it was not possible to follow the star till its advance on the rising curve, Mr. Knott was unable to fix the time of minimum with certainty, but considered the predicted time (16h. 22m.) was pretty correct. He remarks further that Prof. Schonfeld gives 8½h. as the time of decrease, and 13h. as that of increase. If this held for the minimum of February 20, and the decrease began at 9h. 30m., the minimum would not be reached before 18h., and the normal magnitude would not be attained before February 21, 8h. At 6h. 30m. on the latter date he doubted whether the star had recovered its normal brightness, but by 7h. or 7h. 30m. there seemed no doubt about it. Comparing the form of his curve with Prof. Schönfeld's, it appeared that on this occasion the star was longer in falling from 9·4 and 9·9 m. to the lowest point reached, than the observations of Prof. Schonfeld indicated; but Mr. Knott writes doubtfully upon this point, not having previously watched S Cancri through its changes. The next minimum may be expected on March 11, between 15h. and 16h. Greenwich time.

THE MELBOURNE OBSERVATORY.—We have received the nineteenth annual report of the Government Astronomer of Victoria to the Board of Visitors of the Melbourne Observatory. The new transit circle of 8 inches aperture, constructed for that establishment by Mr. Simms, was received in May last, and the mounting was completed early in July. At the time of drawing up the report (August, 1884) there were only wanting some steps and observing chairs, for the instrument to be brought into regular use. It is stated to be very similar in form and dimensions to the transit circles constructed by the same firm for the observatory at Cambridge and for that of Harvard College, U.S. The great reflector was in better condition than at the date of the previous report, nevertheless it is proposed to send the two specula, one after the other, to England, to be re-polished. A number of stars selected by Prof. Auwers had been observed with the old transit circle, to assist in the formation of a fundamental catalogue of southern stars. Mr. Ellery mentions those of Herschel's nebulæ, which had been observed, and of which drawings had been made with the great telescope; the nebula of η Argûs, 30 Doradus, and the "Horseshoe" nebula are included in his list. Pons' comet was observed for position from January 6 to March 18. The completion of the telegraphic determination of Australian longitudes, it is reported, was only waiting a new series of exchanges between Sydney, Adelaide, and Melbourne; New Zealand had been connected with Sydney by a most successful set of time exchanges through the cable. The connection of Brisbane

and Sydney was in progress, and, on this being completed, there would only remain to connect Western Australia, to have the longitudes of all the chief Australian and New Zealand cities and ports determined upon the same system.

Mr. Ellery recommends that a small expedition should be despatched from Melbourne to New Zealand for the observation of the total eclipse of the sun on September 9 in the present year, when the central line passes through Cook's Straits. Sir W. Jervois, the Governor of New Zealand, had promised all the aid he could render in the matter. The Board of Visitors supported an application to the Government of Victoria for the necessary funds. [Full details of the circumstances of this eclipse were given by Mr. Hind in the *Monthly Notices* of the Royal Astronomical Society for January last.]

ASTRONOMICAL PHENOMENA FOR THE WEEK, 1885, MARCH 8–14

(For the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on March 8

Sun rises, 6h. 31m. ; souths, 12h. 10m. 51·6s. ; sets, 17h. 51m. ; decl. on meridian, 4° 42′ S. : Sidereal Time at Sunset, 4h. 57m.

Moon (at Last Quarter at 19h.) rises, 1h. 5m. ; souths, 5h. 40m. ; sets, 10h. 12m. ; decl. on meridian, 17° 25′ S.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. on Meridian
Mercury ...	6 36 ...	11 56 ...	17 18 ...	8 22 S.
Venus ...	6 13 ...	11 18 ...	16 23 ...	11 26 S.
Mars ...	6 28 ...	11 52 ...	17 16 ...	7 44 S.
Jupiter ...	13 46 ...	22 58 ...	6 10* ...	13 8 N.
Saturn ...	9 56 ...	18 0 ...	2 5* ...	21 41 N.

* Indicates that the setting is that of the following nominal day.

March 13, 19h.—Mercury in superior conjunction with the Sun.

RECENT ENGINEERING PATENTS[1]

SIR FREDERICK BRAMWELL stated that he had been determined in his choice of a subject by the consideration that H.R.H. the Prince of Wales had seen fit to appoint him chairman of the Executive Council of the International Invention Exhibition, to be held at South Kensington this year. He therefore proposed to direct attention to some of those objects that ought to be contributed to that Exhibition which were more particularly connected with civil engineering.

Dealing, first, with materials of construction, the President remarked that probably few materials had been more generally useful to the civil engineer, in works which were not of metal, than Portland cement. During the last twenty-two years great improvements had been made in the grinding and in the quality of the cement. As regards bricks, although not now superior in quality to those made by the Romans, there was progress to be noted in the mode of manufacture and the materials employed. The brick-making machine and the Hofmann kiln had economised labour and fuel, while means were being made to utilise the waste of slate quarries. Good artificial stones appeared at last to be produced with such uniformity and power of endurance as to compare favourably with the best natural stone, or were even better, for they could be produced of the desired dimensions and shape, and were ready for use, without labour of preparation. The preference of wood, except in newly-developed countries, was decreasing for one reason, because it was practically impossible to be sure as to obtain anything approaching to the full tensile strength. Many attempts had been made to render timber proof against rapid decay and ready ignition, and it was in these directions alone that progress could be looked for. With respect to preservation from fire, the wooden structures of the Health Exhibition were coated with asbestos paint, and to this their escape from destruction by a fire was due. Leaving the old world materials of stone and wood, attention was directed to that form of iron known as steel. The President remarked that, in his judgment, the making of steel in crucibles was not so satisfactory a mode of obtaining uniformity in large masses as was either of the other two great systems of manufacture—the Bessemer and the Siemens—the two processes which had changed the whole complexion of the iron industry. He further said that, eight years ago, in a lecture he delivered at the Royal Institution, he had ventured to predict that steel made by fusion would supersede iron made by the puddling process, and that the use of iron made would be restricted to the small articles produced by the village blacksmith. The first important revelation in steel manufacture was the ingots shown by Krupp, with other products, at the Great Exhibition of 1851. These showed an extent to which at the time when the production of steel involved the employment of the crucible. Within the last eight years a great improvement had been made by Messrs. Thomas and Gilchrist, which it had been rendered possible to employ successfully for the production of steel, iron derived from ores that, prior to the date of this invention, had been found wholly inapplicable for the purpose. In the manufacture of pig-iron improvements had been effected by increasing the dimensions of the furnaces and the temperature of the blast, by the better application of machinery to the industry, by the total closing of the tunnel-head of the furnace, and by the greater use of the waste gases. Cast-iron, so long used in its alloyed condition of "gun-metal," has, within the last few years, been still further improved by alloying it with other substances so as to produce "phosphor-bronze" and "manganese-bronze," very useful materials for those engaged in the construction of machinery. With the increased dimensions of the main-shafts of engines, and of the solid forgings for the tubes of cannon, obtaining at the present day, composed, as they were, of steel, the operations of the steam-hammers were absolutely harmful, and the blows of even the heaviest hammers were not so efficacious as was possible if applied without blow. The time was not far distant when steel in its molten state would be subjected to pressure, with the object of diminishing the size of any cavities containing imprisoned gases.

Within the period under consideration the employment of testing-machines had come into the daily practice of the engineer for determining, experimentally, the various physical properties of materials—and of those materials when assembled into forms to resist strain, as in columns or in girders.

In those matters which might be said to involve the principles of engineering construction, there must of necessity be but little progress to note. Principles were generally very soon determined, and progress ensued, not by additions to the principles, but by improvement in the method of giving to those principles practical shape, or by combining in one structure principles of construction which had hitherto been used apart.

Taking up, first, the subject of bridge construction—the President thought the St. Louis bridge might fairly be said to embody a principle, novel since 1862, that of employing for the arch-ribs tubes composed of steel staves hooped together. Further, in suspension bridges, there had been introduced the light stay-chain, from which were suspended the linked truss-rods, for the actual work of supporting the load, the rods being maintained in straight lines, and without flexure at their points of their weight. In the East River Bridge at New York, the wire cables were not made as untwisted cables, and then hauled into place, imposing severe strains upon many of the wires, but the individual wires were led over from side to side, each being

[1] Abstract of Presidential Address at the Institution of Civil Engineers, by Sir Frederick J. Bramwell, F.R.S., on January 13.

rain. So far as novelty in girder-construction ie suspended cantilever of the Forth Bridge, onstruction, afforded the most notable instance. see how a rigid bridge, with 1700 feet spans, sity for so much clear headway below, could without the application of this principle. A ple of the use of pneumatic appliances in or foundations was also in progress at the the New Tay Viaduct, the cylinders were being guided through wrought-iron pontoons, l to their berths and were then secured at the e protrusion, hydraulically, of four legs, which ttom, and they, until they were withdrawn, toon from a floating into a fixed structure.

next traced the contest between canals and modes of internal transit, in contrast with rred to the improved rate of transport on itution of steam- for horse-haulage, and by a number of lockages. He also alluded to the ift on the River Weaver, and to a similar Canal de Nenfossé, in France, for overcoming of level, and reducing the consumption of penditure of time to a minimum. The great of late years in canal engineering, was not r improvement, of the ordinary internal canal, of canals such as the completed Suez Canal, in course of construction, the contemplated h canal—all for saving circuitous journeys in ea to another—or in the case of the Manchester king ocean steamers many miles inland. The nal-engineers and railway-engineers was illus- nsal to connect the Atlantic and Pacific oceans ip-railway, the details of which scheme were

truction, the principle adopted in the Liffey at ed to, where cement-masonry was moulded the wall, for its whole height and thickness, ngth forward as could be admitted, having tical limit of the weight of the block. The carried to its place, was lowered on to the been prepared to receive it, and was secured ve and tongue. The apparatus by which the 50 tons each, were raised, and transported to was then described.

sub-aqueous works necessarily led to appliances re the President said a few words about the "used on the "barrage" of the Nile. Beyond tail and the application of the telephone, there ovelty to record in the ordinary dress of the reat step had been made in the diver's art by of the chemical system of respiration. A apparatus had been devised, embracing a which the exhaled breath of the diver was bonic acid. The diver also carried a supply gen to be added to the remaining nitrogen, that which had been burnt up in the process ined with this apparatus, a diver during one which occurred in the construction of the tended into the heading, proceeded along it s (the depth of the water above him being a sluice-door through which the water was tions, and thus enabled the pumps to unwater ether, this man was under water for one hour nutes without any communication with those

pily, cases of sub-aqueous tunnelling where dealt with by ordinary pumping power, and was capable of being cut by a tunnelling dersey Tunnel, in the New Red sandstone, a bes in diameter, a speed of 10 yards in 24 ged, while a maximum of over 14 yards In the experimental Channel Tunnel in a e gray chalk, a maximum speed of 24 yards in the 24 hours on the English side, and on 27½ yards in the same time. In ordinary ce 1862, there had been great progress, by f dynamite, and preparations of a similar der, and by improvements in the rock-drills and air, used in making the holes into which harged. In boring for water, and for many other purposes, the diamond drill had proved of great service. Closely connected with tunnelling-machines were the machines for "getting" coal, which, worked by compressed air, reduced to a minimum the waste of coal, relieved the workman of a most fatiguing labour in a constrained position, and saved him from the danger to which he was exposed in the hand operation. The commercial failure of these machines was due to trade opposition, and it was to be feared that like prejudices would prevent the introduction of the lime-cartridge in lieu of gunpowder.

With regard to the great source of motive power—the steam-engine—it was difficult to point to any substantive novelty since 1862. But the machine had been more and more scientifically investigated, and the results had been practically applied with corresponding advantages. The increase in initial pressure, the greater range of expansion, the steam-jacketing of the vessels in which the expansion took place, had all led to economy. Double-cylinder non-condensing engines were now currently produced, which worked with a consumption of only 2¾ lbs. of coal per I.H.P., or 2·7 lbs. per H.P. delivered off the crank shaft, equal to 82 millions of duty on the Cornish-engine mode of computation. When these results were augmented by the employment of surface-condensation, an I.H.P. had been obtained for as low as 1½ lbs. of coal, and it was commonly obtained, in daily work, for from 2 lbs. to 2½ lbs. But in the use of steam as a heat-motor, the largest portion of the heat passed away unutilised. This defect had been sought to be overcome by a regenerative steam-engine, but it was not successful. Heated-air engines had hitherto only been found applicable where small power was required. Another form of heat-motor—the gas-engine—was daily coming into general use up to 30 I.H.P. By a change in the mode of burning the mixture, and of utilising the heat thereby generated, the injurious shock of the early forms of gas-engine, and their large consumption of gas, were obviated. Comparing a gas-engine with a non-condensing steam-engine consuming 5 lbs. of coal per I.H.P. per hour, and demanding therefore, at one shilling per cwt., only one half-penny for the purchase of coal, the extra cost for working the gas-engine was well repaid by the saving of boiler-space, of the wear and tear of the renewal of the boiler, of the consumption of coal while getting up steam and during meal-times, of the saving of wages, of the freedom from boiler explosions, and of the cessation of smoke production. A motor had been recently tried where no fuel was employed directly, but where a boiler, being filled with water and steam under pressure, had its heat maintained by exposing caustic soda, contained in a vessel surrounding the boiler, to the action of the waste steam from the engine, the result being that, as the moisture combined with the caustic soda, sufficient heat was developed to generate steam and keep the engine working for some time. Trials had been made with this motor for propelling a launch and for working a tramcar.

With respect to other motors, viz. those driven by wind or by water, in France an improvement had been made in water-wheels by which it was asserted that 85 per cent. of all the energy residing in a low fall of water had been converted into power. In turbines also there had been considerable development during the last twenty-two years, and they were very efficient where a high fall of water had to be utilised, or where, in the case of a low fall, great difference in the working head, and in the level of the tail-water, had to be provided for.

Next to the subject of motors came the transmission of power. In its restricted sense, the transmission from one part of a machine to another, reference might be made to the increasing use of multiple-rope driving-gear in lieu of belts, to inclined spur-gear for diminishing noise, and to that kind of frictional gearing to which the name of "nest-gearing" had been given. Where, however, the transmission was to long distances, means were being adopted for supplying power—*i.e.* water under pressure or compressed air—through mains laid down in the streets, in a manner similar to that in which gas and water were now supplied for domestic use; and in New York and other cities of the United States high-pressure steam was similarly conveyed and delivered to the consumers, both for power and for heating.

Sir Frederick Bramwell also remarked upon the continuous rolling of bars of steel for tyres, upon the right way of making boiler-shells and boiler-flues, upon tidal motors, upon "dirigible" balloons, upon the Maxim machine-gun, and upon the application of submarine mines and torpedoes for the defence of seaports. In regard to waterworks, he could not adduce any material improvements in those dependent upon storage, or in

pumping machinery; but in the matter of house-fittings there had been great progress, especially in the detection and prevention of waste of water. With respect to gas as a distributed illuminant, considerable improvements had lately been made, due in a greater liberality on the part of lighting-authorities, and to the use of multiple burners in street-lanterns, by which a greater amount of light was obtained from the same volume of gas. The regenerative gas-burners, and other modes, promised largely to increase the candle-power per cubic foot of gas burnt.

In conclusion, the President stated that, during his term of office, he would do all that lay in his power, as he had done in the past, to uphold the honour, the dignity, and the usefulness of the Institution; and in these efforts he felt satisfied that all the members would cheerfully and gladly assist.

HOW THOUGHT PRESENTS ITSELF AMONG THE PHENOMENA OF NATURE[1]

EVERY phenomenon which a human being can perceive may be traced by scientific investigation to motions going on in the world around him. This is obvious to every scientific man in regard to such phenomena as those of colour and sound, and these simpler cases were first adduced by the lecturer. He then pointed out that the statement is also true of all other material phenomena, and he specially dwelt on the phenomena investigated in the science of mechanics, showing that all the quantities treated of in that science, such as force and mass, prove, when the investigation is pushed far enough, to be expressible in terms of mere motion. He also showed that the prevalent conviction that motion cannot exist unless there is some "thing" to move will not stand examination. It proves to be a fallacious conviction traceable to the limited character of the experience of motions which we and our ancestry from the first dawn of organised thought on the earth have had within reach of our senses. This conviction accordingly has no authority with respect to molecular motions and to some others that have been brought to light by scientific study. He also showed that the "thing" which in common experience moves, proves in every case to be nothing else than these underlying molecular motions, the transference of which from place to place is the only kind of motion which common experience can reach, when unassisted by science.

The intermediate steps between the world external to our bodies and the brain which take place in our organs of sense and nerves can also be ascertained to be motions. And finally, a change consisting of motions takes place in the brain itself, whereupon we become conscious of thought: *i.e.* a change occurs within the brain which would be appreciated as motions by a bystander who could search into our brains while we are thinking, and could witness what is going on there, while all the time the change that we experience is thought. It must be borne in mind that our brain is a part of the external world to the bystander whom we have supposed to be observing what is going on in it. It thus appears that every phenomenon of the external world is reducible to matter and their modifications, while all that is within the mind is thought.

Now this motion to which all other material phenomena are reduced, this motion as it exists in nature, must be distinguished from man's conception of motion, which, after all, is one of his thoughts—a very complex one, no doubt, but not part of the external world. This particular conception in our minds is one remote effect of the motion as it exists outside us, and what we really know of that external cause is that it is a cause which does unfailingly produce this effect if the intermediate appliances of our senses and nerves are also present. Motion, the cause, must no doubt stand in absolutely rigorous relations to its effect, viz. our conception of motion: but it need not be like its effect, the presumption being quite the other way. The lecturer pointed out that, under these circumstances, the simplest and so far the most probable, hypothesis that can be advanced is the monistic hypothesis that this unknown cause is itself thought; and he pointed out that it is no objection to this view that we are unconscious of all the thought here supposed, for this is only to say that it is external to that particular group of interlacing and organised thoughts which we call our own mind, just as the thoughts of the many millions of our fellow-men and of all other animals are external to our little group.

The lecturer accordingly recommended the following hypothesis: (1) as consistent with everything we know, (2) as the simplest hypothesis, (3) as an hypothesis which dispels all the difficulties that encumber the dualistic supposition that there are two kinds of existence, viz. the hypothesis that if a person were armed with adequate appliances to ascertain what is going on in our brain while we are thinking, then what we should experience to be thought is itself the remote cause which determines the intermediate causes of that change within the observer's brain which determines his having that complex thought which we would call perceiving some of the motions in our brain—in short that what he appreciates as motion we experience to be thought.

If this view be correct, it will follow that the thoughts of which we are conscious are but a small part of the thoughts going on even in our own brain, and which would be seen by the bystander holder as motions, the rest being unconscious cerebration as much outside our consciousness as are the thoughts of other people. We are led also to the conclusion that the thought which is going on in the brains of all the animals that surround us, but the "small dust of the balance" compared with what is going on throughout the rest of the mighty universe.

SCIENTIFIC SERIALS

THE *American Journal of Science*, February.—Obituary notice of Benjamin Silliman, son of Benjamin Silliman, the founder of this *Journal*, and long one of its editors, who died in his ninety-first year at New Haven, Connecticut, on January 14, 1885. The organisation and plan of the United States Geological Survey, with a map, by J. W. Powell. The organisation of the present established, comprises: (1) an astronomic and geodetic division, the officers of which are engaged to determine the geographic coordinates of certain primary points; (2) a triangulation corps engaged in extending a system of triangulation over various portions of the country from measured base-lines; (3) a topographic corps, organised into twenty-seven parties for work over various portions of the United States.—Memorial of the late distinguished botanist, George Bentham, by Asa Gray.—Palæontological notes on the material from the St. John group of New Brunswick contained in the Hartt Collection at Cornell University, by Charles D. Walcott.—On the rotation of the equipotential lines of an electric current by magnetic action, by E. H. Hall. The results are given of experiments made during the month of August, 1883, and at intervals since in the physical laboratory of Harvard College, the substances employed being chiefly copper, zinc, certain of their alloys, and steel.—On the use of the term "Esker, or Kam drift," by Henry Kinahan. Both terms are traced to a Keltic root, *eskir* (not *kame*, long, as wrongly pronounced in Scotland and the Lowlands), meaning, in Irish, *crooked* or winding, as the river Cam, while *Eskir* or *Eisir* denotes a small but well-defined ridge.—On the cause of mild polar climates, by James Croll. In this third paper the author discusses the climate of the Tertiary period in so far as affected by eccentricity.—Climate and vegetation of the Cretaceous period.—Notice of the remarkable marine fauna occupying the outer banks of the southern coast of New England, by A. E. Verrill.—Note on a fossil coal plant found at the Pictou deposit in mica schist at Worcester, Massachusetts, by Prof. H. Perry.—The test-well in the Carboniferous formation at Brownville, Nebraska, by Prof. L. E. Hicks.—Review of Newcomb's supplement to Delaunay's "Lunar Theory," by Prof. Stockwell.

THE *Journal of Botany* for February contains a figure of several new or rare species of Desmid to illustrate one of a series of papers on these organisms, by Mr. W. Joshua. It contains also the annual list of new flowering plants published to the locals in Britain in 1884. Most of the other articles descriptive.

thermometers.
prengel pump is used for producing a vacuum,
ably good vacuum has been produced, so that
gauge indicates a presence of one millimetre or
of mercury, the drops of mercury falling in the
engel give rise to a loud metallic hammering
y fall with such unbroken sharpness that those
ns of pump are often troubled by the "fall-
longitudinally through a length of several inches
in itself very remarkable, considering the
tubes and the smallness of the mercurial drops.

If, while this hammering is going on, the glass vessel which is being exhausted and the leading tubes of the Sprengel pump be heated by passing the flame of a spirit-lamp or of a Bunsen burner over them, the hammering immediately ceases, and on looking closely at the fall-tubes it is seen that they are carrying down air which the heat has liberated from the glass walls of the apparatus. The ordinary barometer-gauge is scarcely sensitive enough to show an increase of pressure, but the McLeod gauge readily shows it.

There is another well-known phenomenon connected with the condensation of gases and vapours on the surface of glass: viz. the condensation of a watery film over the glass of electric apparatus, in virtue of which, at temperatures considerably above the dew point, the glass supports are not insulators of electricity. This film of moisture is removed by exposing the glass stems to heat, or to an artificially dried atmosphere. Some years ago, at the wish of Sir William Thomson, I endeavoured to weigh this film of moisture, but was absolutely unsuccessful. The film must be of extreme tenuity. Prof. Quincke has, however, made important researches on the "distance of capillary action" and on some of the properties of these very thin films. His results are given in two papers: *Poggendorff's Annalen*, 108, p. 326, 1859; and *Wiedemann's Annalen*, vol. ii. 1877, p. 145. He finds their thickness to be comparable with 5×10^{-8} cm.

With the view of measuring the quantity of gas condensed upon a given surface of glass, I caused to be prepared in August last a large quantity of fine glass thread. Some of this was of flint glass rod or cane, which was softened in the blowpipe flame, and drawn out on to a wheel. The remainder was of flint glass tubes, drawn out in a similar way. The spun glass was carefully parcelled up in paper and put aside till I should be ready to use it.

On January 31 I put a quantity of the non-tubular glass fibre into a glass tube 2 cm. in diameter and 12 cm. long, and attached it by a glass sealing to a five-fall Gimingham Sprengel pump. The pump, which was in excellent order, was then worked rapidly till I had produced a very good vacuum, which by the McLeod gauge gave me an indication of 0·3 **M** pressure.[1] The pump was then left for about an hour, and at the end of that time, passing one more bottle full of mercury through the pump, I ascertained that the vacuum had not sensibly deteriorated, the McLeod gauge giving identically the same reading as before. This exhaustion was performed without the application of any unusual heat to the tube containing the glass fibres. The temperature of the room was about 56° F.

I now raised the mercury to the upper level and allowed it to flow through the pump, and the drops fell with the well-known loud hammering noise. While this was going on I applied a Bunsen burner to the tube containing the spun glass. In a few seconds the hammering of the mercury ceased, and on applying the test of the McLeod gauge the pressure within the pump was found to have risen largely. I did not, however, obtain a measurement with the gauge corresponding to the maximum pressure of the gas driven off, or to any particular state.

I now proceeded to pump out all the gas I could, working the pump and heating the tube containing the glass fibres strongly. The heating was carried on from time to time till the tube, which was of German glass, showed signs of softening and of falling in; and the glass fibres were likewise, some of them, slightly softened and bent.

The pump was worked for over an hour, the heating being applied, and the gas, which was easily seen being carried down, was collected in a tube made for the purpose, which was fitted on over the upturned ends of the five fall-tubes. At the end of this time the vacuum was again fairly good, though not so good as it was before the heating commenced. The McLeod gauge indicated 1·2 **M**. It was seen that very little more air was being carried down, and I did not wish to push the vacuum farther than, or quite so far as, the vacuum which had been obtained before the liberation by heat of the condensed gas.

The collecting tube was now removed, and the gas obtained was measured and analysed, so far as it was possible to analyse a quantity so small.

The total amount of gas collected was calculated to be, at 15° C. and a pressure of 760 mm., 0·45 of a cubic centimetre. To this a small quantity of strong solution of caustic potash was added, and time was given for absorption. A small quantity of pyrogallic acid was next added, and the further absorption observed. The residue was so small that I could do nothing farther.

[1] **M** standing for one-millionth of an atmo-

The result of the analysis showed 8·24 per cent. of the whole to be carbonic acid gas (absorbable by caustic potash). Of what remained 24·8 per cent. was oxygen (absorbable by pyrogallic acid and caustic potash mixed). The residue, 75·2 per cent., was, I presume, mainly, if not wholly, nitrogen. I ought to remark that my pump was furnished, as is usual, with the phosphoric acid drying tube. The gas, therefore, which I collected was perfectly dry, and I have no way at present of ascertaining how much moisture adheres to the spun glass. In stating the results of the analysis I have made no correction for moisture introduced with the potash solution.

In order to make an estimate of the amount of surface exposed by the spun glass, I measured, with a screw micrometer gauge, the diameters of 200 of the fine glass fibres taken at random. I found them, as I expected from the care with which they had been prepared, fairly uniform, and the average diameter was 7·06 hundredths of a millimetre. Weighing also the 200, and then the whole quantity, I found the whole number of the fibres to be 6370. The average length was 10·25 cm. The surface was thus 1448 sq. cm., or equal to that of a square 38 cm. in the edge.

I am preparing for further experiments on this subject, and hope soon to be able to add to it observations on the amount and on the electric conductivity of the film of moisture condensed upon the surface of glass.

Additional Note.—Since the writing of my former communication on this subject, I have made some further experiments on it, and I beg leave to give an account of the results of one of these experiments.

Having filled a fresh tube with fresh spun glass, I carefully exhausted with the Sprengel pump on January 24, and the exhaustion was kept up till February 5—that is, for twelve days. During this time I frequently tested with the McLeod gauge. A very slight increase of pressure was found during that interval, but it was so slight that I am not able to say that it was greater than that which is observed at all times, even with the Sprengel pump in excellent order, when a vacuum is maintained for several days.

On February 5 I passed three or four bottlesful of mercury through the pump, and had a vacuum of about 0·5 **M.** as shown by the McLeod gauge. I then applied heat, and had instantly an abundance of gas given off from the spun glass. This was collected as before, and analysed.

The number of glass fibres was 15,500, giving an estimated surface area of 3527 sq. centims. The amount of gas given off was 0·41 c.c., which is considerably less in proportion than in my first experiment.

Of this gas it was found that 78·6 per cent. was carbonic acid gas (absorbable by caustic potash). Of the remainder 10·5 per cent. was oxygen (absorbed by pyrogallic acid and potash), while 89·5 per cent. was left unabsorbed, and may be supposed to be mainly nitrogen.

The very large proportion of carbonic acid gas is remarkable, and it is difficult to account for, unless we may suppose that it was taken up by the glass in large quantity during the operations of drawing out the glass into fibres and inclosing it in the containing tube—operations during which there was, in these preliminary experiments, an abundant supply from the blowpipe flames.

Chemical Society, February 5.—Dr. W. H. Perkin, F.R.S., President, in the chair.—A lecture was delivered "On Chemical Changes in their relation to Micro-Organisms," by Professor Frankland, F.R.S., a plant being defined as an organism performing synthetical functions, or one in which these functions are greatly predominant; an animal, as an organism performing analytical functions, or one in which these functions greatly predominate. The micro-organisms were classed by the lecturer among animals. Their life essentially depends upon the taking asunder of more or less complex compounds, resolving them into simpler compounds at the expense of potential energy. As micro-organisms are commonly termed "ferments," and their analytical operations "fermentations," it is necessary to sharply distinguish between organised ferments and certain bodies which bring about analogous chemical changes, but which are not only not organised, but exist in solution. These latter, or "soluble ferments," as they are commonly termed, are said to act by contact; they produce certain chemical changes in the fermentescible substances without themselves furnishing from their own substance any of the products of change; the effects they produce are essentially analytical, consisting in the assimilation of water and the splitting up of the fermentescible substance into two or more new molecules, and may be brought about by purely chemical means. They differ only, or chiefly, from the organised ferments in that they are unorganised and do not increase in amount during their action upon fermentescible substance, of which a very large, although limited, quantity may undergo transformation by the action of a very minute quantity of the ferment. A list of changes brought about by micro-organic ferments was given. In that portion of the animal kingdom with which we are best acquainted, oxidation is the essential condition of life: it is the kind of action by which the latent changes actual into potential energy. The changes effected by micro-organisms are essentially of the same character as those brought about by the higher orders of animals: that is to say, they are all changes by which potential becomes actual energy. With one or two exceptions, the chemical changes effected by micro-organisms—unlike those produced by soluble ferments—cannot be brought about by other means. The observations of Hatton and others have shown that micro-organisms retain their vitality in presence of a variety of substances which would prove fatal to higher animals; the unexpected fatal effects of pongy iron would seem to promise, however, that there are substances fatal to bacterial life which have no toxic effect on more highly organised animals. It has not yet been shown that any degree of cold, however intense, is fatal; animation may be suspended, but it is restored when the temperature rises. With regard to heat, the lowest fatal temperature recorded is 40° C., but many species can withstand much higher temperatures. Chloroform and compressed air are said to arrest their action, but have no influence in preventing the changes brought about by unorganised ferments. The position of micro-organisms in nature is only just beginning to be appreciated; their study both from chemical and biological points of view is, however, of the highest importance to the welfare of mankind, and leads the inquirer right into those functions of life which are still shrouded in obscurity. In the course of the lecture the best known micro-organisms and the chemical reactions due to them were passed in brief review. Prof. Frankland also referred to the following results of an experiment made in the month of June, in which fresh urine was allowed to stand for 25 days in a clean glass vessel:—

	Reaction.	Organic carbon.	Nitrogen as urea and other organic matter.	Ammonia.	Microscopical observations.
Fresh urine	43·70	943·81	1060·27	142·40	No bacilli.
" after 1 day		940·46	1095·95	130·95	"
" " 3 days		858·76	1066·70	136·30	"
" " 5 "		849·70	963·36	355·35	Sparse bacilli.
" " 7 "		739·82	764·93	388·10	Numerous bacilli.
" " 10 "		623·09	744·94	405·80	Very numerous bacilli.
" " 14 "		559·22	581·44	576·64	Very numerous bacilli.
" " 16 "		530·68	498·03	881·87	Mostly still.
" " 18 "		495·01	358·25	990·78	"
" " 21 "		466·43	278·22	1105·75	All dead or still.
" " 23 "		451·43	247·45	1017·25	"
" " 25 "		460·78	253·90	1050·50	"
After allowing for evaporation	27·80	546·77	717·60	805·03	
Residue left on evaporation and dry-ing at 100° C.	205·5				

The results of these observations and determinations also

ng the month of June show conclusively that, e development of *Bacillus ureæ*, the chemical he urine remained practically unchanged; but nce of micro-organisms, a diminution of organic nsference of nitrogen from the organic to the immediately began. As regards rapidity, this *part passu* with the density of population, and num about the 12th day; for during the three th) nearly 10 per cent. of carbon disappeared, a 85 per cent. of the organic nitrogen became r the 14th day the rate of change became much 8 h day the bacilli were mostly either dead or st on and after the 23rd day no more moving

Altogether the quantity of carbon converted nhydride, after allowing for concentration of evaporation, amounted to 597·04 parts per id, or 63·3 per cent. of the total quantity; antity of organic nitrogen converted into 546·19 parts per 100,000, or 50·6 per cent. These proportions show that all the organic ed in the urea was not converted into doubt escaped as free nitrogen, in accordance tton's observation. In the original urine the ganic carbon to organic nitrogen was as 1 : 1·15, e action of the bacilli, it was 1 : 0·62. Prof. on said that the main difficulty met with in study- m cro-organisms arose from the fact that it was and often impossible to distinguish between ms. Chemists might naturally turn to biologists atter, but biologists must admit the existence of We are fully acquainted with the life history of genic organism—*Anthrax bacillus*; of this, we know, however, a great deal. The method ogists in studying pathogenic forms was, in the prepare a pure cultivation of the organism, and ne proof that the organism produced its proper sferred to a living animal. The morphological eria with plants could not be questioned, but he eally of little consequence for practical purposes organisms were regarded as animals or plants; know is, what are the conditions under which produced, and its life history. He was in the them microphytes, as being a neutral term.—ester was astonished at the definite way in which had classed the ferment organisms with animals. e led to regard them as plants from examining to other organisms. He agreed with Prof. "microphyte" was a good name for them, ecisely for the same reason, but because it really lant. He stated that it was held hitherto that a uced the ammonic change in urine, and not a ed by the lecturer. For the purpose of chemical t was essential to have a pure cultivation. It the nitrifying organism had not been isolated; d only been inferred, and it had never been parated and identified, although inconclusive observations purporting to inform us as to the ganism had been published.—Dr. Brunton said ghly probable that the symptoms occurring in were due to poisons formed by the action of not directly to the organisms themselves. This ably the case in cholera. Micro-organisms may nbrances fatal to themselves, *e.g.*, phenyl com- is also the case with higher organisms, the e urine in man being often attended with fatal gh cholera was very probably due to the presence ns, the symptoms were so very like those pro- in poisons, that it was very difficult to diagnose ing by arsenic from cholera cases. The cholera baldy of an alkaloidal character and related to

Pepsin converted albuminoids into peptones, ortant to note that Brieger had observed that alkaloid having an action similar to curare was peptic digestion, and an alkaloid having a had been obtained from human urine. These it probable that alkaloids might be formed in the and absorbed into the general circulation. Prof. that the question whether the micro-organisms in plants or animals was to him a matter of in- pared to the question—what was the exact nature of the action by which the organism effected the chemical change? He desired to point out that in certain cases, as in the ammonic conversion of urea, the same change, in this case the conversion of urea into ammonium carbonate, was effected, on the one hand, by a micro-organism, a micrococcus or bacillus, and on the other hand by an unorganised ferment. His friend Mr. Sheridan Lea informed him that he had evidence of both these causes of ammonic conversion of urea. Now, was the action in both cases the same? The idea had naturally occurred that the organism produced its effect by producing an organised ferment. But all attempts to prove the production of such a secretion, so to speak, of a ferment had failed. If such a ferment were produced, it was destroyed or disappeared during its action, whereas ordinary unorganised ferments such as pepsin, &c., were not destroyed at all during their activity, or were destroyed very slowly. On the whole, the probability was that the micro-organism and the unorganised ferment produced the same result in different ways; ought not the *difference* to offer the key for solving the problem? He further desired to remind the Fellows that actions similar to those of these micro-organisms were continually being carried on by the constituent elements of man and other macro-organisms, and would wish, in illustration, to call their attention to the act of secretion by a secreting cell, such as the pancreatic cell. We had evidence that certain constituents of pancreatic juice existed in the cell, not in the form in which they appear in the juice itself, but in an anterior, more complex condition. Thus trypsin occurs in the pancreatic cell not as trypsin but as trypsinogen. Now this trypsinogen, and also probably other "mothers" of the constituent of the juice, exist in the protoplasm of the cell as *discrete granules, lodged in the meshes of the protoplasm, separated from the protoplasm by films of fluid.* Yet the protoplasm, stirred by some nervous impulse, is able to produce a change in these granules, so that they are discharged to form the secretion. How does the protoplasm work upon these granules? Does it discharge something into the fluid of its meshes, which something acts upon the granules? or does it work upon the granule through the film of fluid surrounding the granule, by something which is a sort of "action at a distance"? The action, then, in this case is very comparable to the action of the micro-organisms in question. It is for the chemists to throw light on the exact nature of the changes produced, and, when this is done, we may hope to learn how the change is brought about; but not until this is done.—Mr. Thistelton Dyer said that from the botanist's point of view he was struck with the universality of fermentative changes. Though they were so predominant a feature in the life of the lower plants, this was only an extreme manifestation of what, perhaps, all plants were capable of, if the conditions demanded it. Thus Pasteur, following up an experiment of Béraud's, found that a rhubarb leaf in an atmosphere of carbon dioxide yielded, after 48 hours, though apparently unchanged, small quantities of alcohol. The breaking up of molecules of large thermic equivalent into those of less, supplies the energy needed for the continued life of the tissues, and is the *raison d'être* of the process. But plants also set up fermentative changes external to themselves, as it were incidentally and without any obvious benefit. The investigation of Beyerinck on the production of gum by plants yielded most remarkable results. It is due to a disease which is highly contagious, and which is caused by a fungus (*Coryneum*). This produces a ferment which changes the cell-walls into gum. But what is most remarkable is that even after the disappearance of the fungus which initiated the changes, the the cells of the host plant take on a morbid habit of growth, and themselves continue the production of the ferment and therefore of gum to their own hurt. The problem is here of the most complicated kind. The series is ended by cases such as that of *Withania coagulans* (and many others are now known), where plants throw off, as bye-products of their metabolism, ferments as effective as rennet, without deriving any perceptible advantage from their possession. That plants use in working up their reserve-proteid proteolytic ferments just as animals do, cannot be doubted. But even these they occasionally, as in the Papaw, produce in utter disproportion to their own possible requirements. Mr. Warrington said with regard to the difference between animals and plants, he thought the fact had been somewhat overlooked that plants are able to obtain their nitrogen from such simple compounds as ammonia and nitrates, whereas animals appear to require to have the nitrogen presented to them in an albuminoid form. As to the nature of the nitrifying organism, Muntz and Schlesing claim to have isolated it and have described it. A friend who

had microscopically examined his purest cultivations at Rothamsted, had been unable to find bacilli, but they appeared to contain a micrococcus. [Prof. Lankester, interposing, remarked that the growth sent to him by Mr. Warrington consisted of bacilli, and nothing else.] In explanation, Mr. Warrington said that in one of his earlier papers he had mentioned that white films appeared on some of his solutions. Prof. Lankester had examined these, but he had since found that the bacilli of which they consisted were incapable of nitrifying ammonia. Latterly he had followed Dr. Klein's method, and had introduced the infecting matter into the sterilised cultivation liquid by means of a capillary pipette, which was pushed through the cotton-wool plug closing the tube or flask; since he had done this, the films referred to had never been formed. Dr. Thudichum agreed that the ammonic change was produced in urea by a micrococcus. The study of microphytes and of the chemical changes produced by them in the human body and in the bodies of animals was of the greatest importance. He questioned whether their action was always so specific, however, as was commonly supposed. He would also call attention to the fact that one micro-organism will kill another; thus, after plastering wine, in consequence of the removal of the tartrate, the microphyte which produces ropiness is crowded out by alcoholic forms. Dr. Stevenson called a tention to the importance of obtaining more information as to the alkaloidal bodies formed by the action of micro-organisms. Prof. Frankland replied that he did not mean absolutely to say that in his experiments the work was done by the *Bacillus ureæ*, but the diagram was a faithful representation of what he saw; he attributed the action to the particular organism, because it commenced when the organism appeared, and ceased when the bacilli became motionless. The necessity of studying the actions of pathogenic organisms had been prominently brought forward in the discussion. He thought there was a substantial difference between the class of chemical changes effected by plants on the one hand and by animals on the other; animals more particularly consumed as food those compounds in which much energy was stored up.

Geological Society, February 11.—Prof. T. G. Bonney, F.R.S., President, in the chair.—Arthur William Clayden, Samuel Rided, and H. W. Williams were elected Fellows of the Society.—The following communications were read:—The Tertiary and older peridotites of Scotland, by John W. Judd, F.R.S., Sec.G.S. The very interesting rocks known as "peridotites" have been regarded by many petrographers as peculiar to, and, indeed, characteristic of, the older geological periods; but in the Western Isles of Scotland there occur a number of rocks of this class, constituting portions of intrusive masses, which the author, in a previous paper, has shown to be the central cores of Tertiary volcanoes of vast dimensions. These Tertiary peridotites are most intimately associated with the gabbros and dolerites, the felspathic and non-felspathic rocks passing into one another by insensible gradations, and the rocks of either class being intersected by veins of the other. The peridotites exhibit the same varieties of microscopic structure as the associated gabbros and dolerites, these structures being described under the names of "granitic," "ophitic," and "porphyro-granulitic." The felspars, which are rare in the peridotites, are intermediate in composition between labradorite and anorthite; they rarely, however, exhibit evidence under the microscope of being built up of lamina belonging to different species. The study of the lamellar twinning, which is a common, but by no means universal, character in these felspar crystals, points to the conclusion that it has been induced by pressure or strain, like the similar structure in rock-forming calcite. The pyroxenes are represented by many varieties, both of the monosilinic forms (augites) and the rhombic forms (enstatites), the former being by far the most abundant. The olivines below are, for the most part, highly ferruginous varieties. The spinellids, magnetite, chromite, and picotite occur in these rocks, as do also titano-ferrite and its alteration-products. Among the accessory constituents biotite is the most abundant. It was shown that each of the minerals of these rocks is found to undergo remarkable changes as we pass from the superficial to the central portions of these intrusive rock-masses. The most important of these changes is that for which the author proposed the name "schillerization." It consists in the development of microscopic inclosures, in the form of plates and rods, along certain planes within the crystal, giving rise to metallic reflections or a play of colour. The felspars, pyroxenes, and olivines are all found to be affected in this way when they have formed the deepest parts of these volcanic cones. In this way common augite is seen at gradually increasing depths, passing into the deep-brown variety known as pseudo-hypersthene. The last-mentioned substance presents a curious mimicry of rhombic hypersthene and paulite, which is the schillerized form of a ferriferous enstatite. The Tertiary peridotites present many variations, not only in their structure, but also in their mineralogical constitution. Among them occur examples of the rocks which have received the names of dunite, picrite, and lherzolite, with some curious types composed of felspar and olivine. Among the older peridotites of Scotland a new and very interesting type is described from near Loch Scye in Caithness. It appears to have been originally a mica-picrite, but the whole of the original minerals have been converted into pæmmorphic, firstly by schillerization, and subsequently by amphibolization and serpentinization. In conclusion, it was pointed out that the discrimination between the effects of the changes described as schillerization, and those known as uralitization, amphibolization, serpentinization, and kaolinization is of the utmost importance, not only to the petrographer, but to the mineralogist.—Boulders wedged in the Falls of the Cynfael, Ffestiniog, by T. Mellard Reade, F.G.S.

Royal Microscopical Society, February 11.—Anniversary Meeting.—The President (Rev. Dr. Dallinger, F.R.S.) in the chair.—The Report of the Council showed a remarkable development of the Society during the last six years, 301 new Fellows being elected as against 97 in the preceding six years. The income showed also an important increase.—Dr. Carpenter, in moving the adoption of the Report, referred also to the success which had attended the Society's *Journal*.—Dr. Dallinger then gave his annual address to what was probably the largest gathering of Fellows ever assembled on a similar occasion. After briefly referring to the increased interest lately manifested in the study of minute organisms and recalling the characteristics of the doctrines of abiogenesis and biogenesis, he passed rapidly in review the results of the observations of Tyndall, Huxley, and Pasteur as bearing upon these questions, and called attention to the observations of Buchner as to the transformation of *Bacillus anthracis* and *Bacillus subtilis*, and *vice versâ*, and referred with approval to Dr. Klein's criticisms thereon. Having spoken of the desirability of careful and continuous study of this class of organisms, and the importance of endeavouring to establish the relation of the pathogenic form to the whole group, he said he should be better able to deal with the subject by recording a few ascertained facts rather than by making a more extended review, and he therefore devoted the main part of his address to a description of "the life-history of a septic organism hitherto unknown to science." In his observations of this form—extending over four years—he had the advantage of the highest quality of homogeneous lenses obtainable, ranging from one-tenth to one-fiftieth of an inch, his chief reliance being placed upon a very perfect one-thirty-fifth of an inch; and from the continuous nature of the observations, as well as the circumstances under which they were carried on, dry lenses had for the most part to be employed. Having in his possession a racer-vion of cod fish in a fluid obtained from boiled rabbits, he found at the bottom of it, when in an almost exhausted condition, a precipitate forming a slightly viscid mass, to which his attention was particularly directed. It was seen to contain a vast number of *Bacterium lineare*, but on examination with a one-tenth inch objective showed that it also contained a comparatively small number of intensely active organisms—one being discovered in about eight or ten drops of the sediment. These measured 1-10,000th of an inch in length by 1-19,500th of an inch in breadth. The fluid had originally been kept at a temperature of 90° to 95° F., and it was noticed that, when placed upon a cold stage under the microscope, the movements of the organisms became gradually slower, until at last they entirely ceased; the necessity, therefore, arose for the use of a warm stage, and the very ingenious contrivance, by which a continuous and even temperature was maintained within the one-tenth of a degree, was exhibited. The greatest difficulty in the matter was, however, experienced in obtaining specimens for observation, in order to be able to trace them from their earliest to their latest stage.—The President then explained, by means of an admirable series of illustrations projected upon a screen by the oxy-hydrogen lantern, the life-history of the organism to which he had referred, exhibiting it first as a translucent, elliptic, spindle-shaped body, with six long and delicate flagella, the various

ve specimens were drawn giving a very porpoise-like movements. The various ed in making an attack upon a portion were also shown, the movements quite by their rhythmical character. The lagella in the production of the move- ained, distinct evidence being afforded of on, at least of those behind. The pro- ated in all its observed stages from the triction to that of final and complete ing performed within the space of eight cription of the process of fusion from o organisms to their entire absorption as well as their transformation into a dually decreased in size in consequence in of granules in its wake as it moved velopment of these granules was traced quque and spherical form to that of the n first shown, the entire process being our. Experiments as to their thermal whilst the adults could not be killed by 46° F., the highest point endured by the nations of a variety of other modes of rious researches on similar forms were of multiple division and a similar pro- nism contained in an investing enve- luded his address, which was listened to est attention, by remarking that, though n and their progress traced, the *modus* le. titute, February 21.—Francis Galton, chair.—A paper on the race-types of bbauer, was read. The opinion that t their blood unmixed is based chiefly s almost at once recognised amongst m the earliest times, however, we find Abraham's son, Ishmael, was the off- ng; Joseph married an Egyptian, and id descends from Ruth, the Moabitess, Hittite woman, and he himself had ften reminded in the Bible of the non- in contact with the Israelites, and un- e" increased the mixture of races by At Rome the conversions were the converts frequently married Jews. eed of intermarriages in later times ans of various races. The differences uguese Jews and the German-Polish in the middle ages they were believed have descended from different tribes pectively. But the Italian Jews, both d between the rough German and the there is no evidence of any systematic ribes. The pronunciation of Hebrew variation is believed by Dr. Neubauer of the language spoken by the sur- difficulties of obtaining accurate mea- r great, and but few skulls have been however, goes to disprove the exist- pe, uninfluenced by contact with the y dwell.—Mr. Joseph Jacobs read a acteristics of modern Jews. After ses of Jews now existing, the inquiry ics and anthropometry of the Ash- more than nine-tenths of the whole fecundity and vitality were found to and were therefore only secondarily l influences was found, however, in the fact that mixed marriages between Jews and Christians are infertile. Jews enjoy no immunity from any special diseases, but they are more often colour-blind, blind, deaf, and insane than others, owing, perhaps, to their life in cities and to their frequent inter-marriages. Jews were then shown to be the shortest of all Europeans except the Magyars, and to have the narrowest chest. Their skulls are mostly brachycephalic. An examination of over 100,000 Jews showed that they have darker hair and eyes than those of any nation in Northern Europe, though nearly one-fifth of the Jews have blue eyes, and they have nearly twice as many red-haired individuals as the inhabitants of the Continent. A number of composite photographs of Jewish boys, prepared by Mr. Galton, were exhibited to show the Jewish type, and were compared with early representations of Jews in Assyrian art. The Jewish face was said to be a combination of Semitic features and Ghetto expression. Turning to the question of the purity of the race, it was pointed out that this depended on the number of proselytes made by Jews in ancient and mediæval times. The earlier proselytes, before the foundation of Christianity, were mostly fellow-Semites, and would not affect the type, while the numbers made afterwards were too small to modify the race, owing to their infertility and the tendency of the offspring to revert to the Jewish parent. A considerable number of Jews, the Cohens, or descendants of Aaron, were not allowed to marry proselytes, and must consequently be tolerably pure. The general conclusion reached was therefore in favour of the purity of the Jewish race.

Royal Meteorological Society, February 18.—Mr. R. H. Scott, F.R.S., President, in the chair.—Messrs. H. B. Baker, M.D., S. Dixon, R. Foster, and B. O. Meek, F.L.S., were elected Fellows of the Society.—The following papers were read:—How to detect the anomalies in the annual range of temperature, by Dr. Buys Ballot. The author shows that it is most likely that only a long-continued series of observations can give some evidence of an interruption of rise and fall, especially in latitudes where the temperature of the same day in different years may differ by 20° C., as in St. Peter-burg.—Cloud observing, by D. W. Barker. As there is a great deal of confusion amongst cloud-observers, not only as to the particular names of clouds, but more especially with regard to their movements, the author recommends that there should be two simple divisions, viz. "stratiform" and "cumuliform." To the stratiform belong all the higher forms of cloud and a few of the lower; to the latter belong the typical cumulus cloud always seen in the lower atmosphere. From the result of numerous observations the author's conclusion is that the actual normal action of the cirro-filum cloud is along the line of filature, and that, knowing the bearing of the V or radiating point, the direction of its motion can be at once inferred. In all cases the V point first formed in the point from which the cloud is coming, but it will frequently be noticed that threads first appear parallel to a certain point on the horizon, and in all sorts of positions between this and the central V point.—A suggestion for the improvement of radiation-thermometers, by W. F. Stanley. The author suggests that the radiation-thermometer should indicate the amount of heat radiated by the sun upon a metal ball of a certain size, this being an object easy of uniform reproduction by mechanical means. For experiment he made three hollow copper balls, which were cast with ordinary filed cores, and were of different weights. These balls were turned to exact external diameter of 1·4 inch, with similar necks of the insertion of thermometers. The surfaces were oxidised by heating to resemble the oxidation produced by the atmosphere. In each of these balls a similar thermometer was inserted, closing around the neck just sufficient to keep it steady by cotton thread soaked in paraffin. The three thermometers thus inclosed in the metal balls, when exposed to sunshine and placed at two inches above a piece of black board, appeared to register, under similar conditions, exactly alike. The experiments for three summer months gave from 6° to 11° difference between the sun and shade.

Entomological Society, February 4.—R. McLachlan, F.R.S., President, in the chair.—The President returned thanks for his election, and nominated Messrs. Dunning, Stevens, and Weir as Vice-Presidents for the coming year.—Two new members were elected.—Mr. J. W. Slater exhibited a specimen of *Polymmatus chrysais* from Aberdeenshire.—Rev. A. Fuller exhibited a collection of insects captured along the line of the Canadian Pacific Railway.—Mr. W. Cole exhibited a wasp's nest which appeared to have

been inhabited by *Vespa norvegica* and *sylvestris* in common.—Mr. W. L. Distant exhibited a series of wings of Indian butterflies, received from Mr. de Niceville, showing the differences between broods of the same insect in the wet and dry seasons respectively, which had hitherto been generally regarded as distinct species.—Mr. E. A. Butler exhibited egg-cases of three species of *Mantidæ* from Bechuanaland.—Mr. W. F. Kirby (on behalf of Herr Buchecker, of Munich, who was present as a visitor) exhibited three volumes of drawings of *Hymenoptera*.—Mr. H. T. Stainton exhibited specimens of *Chauliodus insecurellus* from Gascony.—Mr. T. R. Billups exhibited various English *Ichneumonidæ* and *Hemiptera*.—Papers read:—Mr. G. F. Mathew, on the life-history of *Papilio Schneideri*, *P. Godefroyi*, and *Xuthisa Semeo*; and Mr. G. Lewis, on a new genus of *Hisperidæ* from Japan.

EDINBURGH

Royal Society, February 16.—Mr. John Murray, Vice-President, in the chair.—Mr. W. E. Hoyle read the first part of a paper on the Cephalopoda of the *Challenger* Expedition. Mr. Hoyle confined attention in this paper to the octopods. Nineteen of these are new to science.—Sir W. Thomson gave a communication on energy in vortex motion. This subject he treated under five heads:—(*a*) energy in vibrations; (*b*) unlimited augmentation of energy of a simply continuous fluid mass in a space of given shape, by changes from and back to this shape; (*c*) annulment of energy under same conditions; (*d*) reduction of energy to absolute minimum in a multiply continuous space of given shape; (*e*) unlimited augmentation of energy in a multiply continuous space.—Dr. Thomas Muir submitted the first part of an exhaustive investigation into the theory of determinants in the historical order of development.—Dr. Muir also, in a paper on bipartite functions, developed a new notation for the expression of quantics, and proceeded to exemplify its use by applying it to the simplification of the proof of Galois's theorem regarding the continued fraction representation of the roots of an equation.—A letter from Prof. Michie Smith was read. He observed the zodiacal light from the top of Dodabettah. No bright lines were seen, and the light did not appear to share in the diurnal motion of the heavens, for it was seen unaltered in position for four hours after sunset. Prof. Smith also showed that in a condensing mist the air-potential is uniformly and markedly higher than the average for the time of day, while the reverse occurs in an evaporating mist.—Prof. Tait gave experimental proof of Sir W. Thomson's theory of the equilibrium of vapour with a liquid under surface-tension by means of two atmometers, in one of which artificial condensation was produced, while under the atmospheric conditions at the time evaporation would be going on in both.—Mr. John Aitken exhibited a new apparatus for the combination of colours.

PARIS

Academy of Sciences, February 21.—M. Rolland in the chair.—Annual elocution, by M. Rolland, President of the Academy for 1884. The chief topics touched upon were the life and work of the late distinguished members of the Academy.—M. J. B. Dumas, MM. du Moncel, Wurtz, and Thenard; the aerostatic essays of MM. Renard and Krebs, which were regarded as marking a new era in aërial navigation; M. Janssen's action in reference to the universal meridian adopted at the recent Congress of Washington; the outbreak of cholera in the south of France and in Paris; M. Pasteur's experiments with the charbon virus and rabies; the progress of electric discoveries.—Announcement of the prizes awarded for the year 1884. Amongst the successful competitors were MM. Maneu and Hamusse (mechanics); M. Bailly (traité de balistique rationelle); M. Riggenbach (mountain railway); M. Jules Hoüel (contributions to pure mathematics); M. du Rocher du Quarego (improvement in screw steam navigation); M. Radau (astronomy); M. Ginzel (lunar physics); M. G. Cabanellas (theory of applied electricity); M. Alfred Durand-Claye (statistics); M. Chancel (organic chemistry); M. Emile Rivière (geology); M. Otto Lindberg (botany); M. P. Fischer (zoology); M. Testut (medicine and surgery); Dr. Cadet de Gassicourt (diseases of infants); M. Tourneux (embryology); MM. Cadiat and Kowalevsky (anatomy); MM. Joly et and Laffont (experimental physiology); Capt. H. Berthaut (physical geography); M. Marsaut (improved safety lamp for miners); M. de Tastes (meteorology); Dr. Nels (geographical exploration); M. J. Boussingault (applied chemistry).—Programme of the prizes prepared for the years 1885, 1886, 1887, and 1893. Amongst these is the sum of 100,000 francs [illegible] M. Breant in 1849, and still unawarded, "to who shall find an efficacious remedy for Asiatic cholera, or di cover the causes of this terrible scourge." To secure th able prize it will be neces ary (1) to find a means of Asiatic cholera in the immense majority of cases; (2) indicate with absolute certainty the causes of Asiatic cholera that by their suppression the epidemic shall cease; (3) co cover a certain prophylactic as infallible, for instance, as cination for small-pox.

GRATEFUL—COMFORTING.

COCOA

THE CELEBRATED

Is unrivalled for Gardeners', Foresters', Farmers', Joiners', and household use. It requires no oil. Sharpens with a spittle or water. Forms a fine sharp edge; no humbug about this. Has stood the test of ten years' use in Homes for Axes, Hedge Knives, Razors, Penknives, and Plane Irons. Honourable Mention, Paris Exhibition, 1878; and Bronze Medal, Edinburgh International Exhibition, 1884. Ask your Ironmonger or other nearest shop to get you one, and give my address; if he won't, drop me a line.

MADAGASCAR AND FRANCE.

With some Account of the Island, its People, its Resources, and Development.

By GEORGE A. SHAW, F.Z.S., London Mission, Tamatave.

With many Illustrations and a Map.

This book is of unusual interest. Mr. Shaw traces carefully the origin and history of the French claims in Madagascar, and enables his readers to estimate accurately both the French and Malagasy positions in the conflict. The chapters on the "Origin of the Malagasy," "Malagasy Civilization," "The Present Civil and Religious State of the Malagasy," "The Fauna," and "The Flora of Madagascar" are full of attractive reading. The book has throughout the vividness of an eye-witness, and the accuracy of one who writes from first-hand knowledge, while a personal interest is given to much of it from the prominent part played by Mr Shaw himself in the events described.

S. N. STOUT.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

* Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the Beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

ELECTRIC LIGHTING. — Manufacturers

and others possessing spare power, and desirous of lighting their Works economically by Electricity, should apply for Price List of Dynamos and Accumulators, for Arc or Incandescence Lighting, to the "JARMAN" ELECTRICAL COMPANY, Mackintosh Lane, Hunnerton, London, E.

ELECTRIC LIGHTING AND ELECTRO-PLATING.

—The "JARMAN" ELECTRICAL COMPANY are prepared to SUPPLY DYNAMOS for Lighting or Plating on the PURCHASE-HIRE SYSTEM, to suit the convenience of many purchasers. Electro-plating and Electro-gilding, old or new goods, in any quantity.

MINERALS AND STONE IMPLEMENTS.

MR. BRYCE-WRIGHT begs to call the attention of his Clients and the Public to his large Series of

MINERALS AND STONE IMPLEMENTS,

from which single specimens can be selected.

Elementary Collections of Minerals, Fossils, and Rocks from £1 upwards.

N.B.—These Collections obtained the Prize Medal, 1862.

GEMS AND PRECIOUS STONES OF EVERY DESCRIPTION.

BRYCE-WRIGHT,

Mineralogist and Expert in Precious Stones,

104, REGENT STREET, LONDON, W.

MINERALOGY AND GEOLOGY.

Mr. HENSON'S Latest Arrivals are :—

Very Fine DOUBLY-TERMINATED CRYSTALS of ZIRCON, 1½ inches long, 3 square; BERYLS, DIOPTASE, UWAROWITE, WALUEWITE, NATIVE SILVER, HERIDERITE, Very Brilliant RUTILES, CHALCOSIDERITE, and NATIVE COPPER, Cornwall; POLISHED JADE and GREEN AVENTURINE, GROUPS and SINGLE CRYSTALS of STIBNITE, Japan; "SHERRY" COLOURED TOPAZES, Siberia.

A Large Series of BOOKS, also MICROSCOPIC SECTIONS of the same.

Lists on Application Hammers, Chisels, and Hammer Straps.

PRIVATE LESSONS AND EVENING CLASSES.

BLOWPIPE CASES AND APPARATUS. Catalogues free.

SAMUEL HENSON,

277, STRAND, LONDON,

Opposite Norfolk Street.

SCIENCE AND ART DEPARTMENT

50 PER CENT. GRANT FOR THE PURCHASE OF STANDARD COLLECTIONS AND APPARATUS FOR TEACHING GEOLOGY AND MINERALOGY. NEW LISTS and FORMS on which the Application is to be made supplied by

THOMAS J. DOWNING,

Geologist, &c.,

38, WHISKIN STREET, LONDON, E.C. (over Quarter of a Century).

SIX PRIZE MEDALS

AWARDED FOR GEOLOGICAL COLLECTIONS.

Geological Collections especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.

New and Rare Minerals constantly arriving from all parts for selection in Single Specimens.

ROCK SECTIONS AND ROCK SPECIMENS:

The Largest Variety in England.

New Catalogues and Lists on application to—

JAMES R. GREGORY,

88, CHARLOTTE STREET, FITZROY SQUARE, LONDON.

Established 27 Years in London.

SUNSHINE RECORDERS.—For UNIVERSAL and for FIXED LATITUDES—fitted with Prof. Stokes' Zodiacal Frame, as adopted by GOVERNMENT, the METEOROLOGICAL COUNCIL, and many private Observatories. Price Seven to Twelve Guineas; 400 Cards, 9s.—Apply to E. J. LECKY, care of KOOLAAT, COPE & Co., Northumberland Street, Strand. Full Trade Discount.

LIVING SPECIMENS FOR THE MICROSCOPE

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM

who has last week sent to his subscribers the Larvæ of a Marine Worm (Spio), with sketch and description. He has also now on hand Cristatella mucedo, Stephanoceros Eichornii, Brachionus urceolaris, Lophopus crystallinus, Cordylophora lacustris, Spongilla fluviatilis, Vorticella globularis; also Aurelia, Hydra, Vorticella, Crayfish, and other Specimens for (Huxley and Martin) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Ten Parts, 1s. each.

BOOKS (Secondhand), Miscellaneous, Re

mainders, &c.—C. HERBERT, English and Foreign Bookseller, 10 Gatwell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchment purchased.

THE SCIENTIFIC RESULTS OF THE VOYAGE OF H.M.S. "CHALLENGER."

Now Ready, "Zoology," Vol. XI. (with numerous Illustrations in Lithography and Chromolithography), in Royal 4to. Price 50s. Cloth.

REPORT ON THE SCIENTIFIC RESULTS of the VOYAGE of H.M.S. "CHALLENGER" during the YEARS 1873-76, under the command of Captain G. S. Nares, R.N., F.R.S., and Captain F. T. Thomson, R.N. Prepared under the superintendence of the late Sir C. W. Thomson, F.R.S., and now of JOHN MURRAY, one of the Naturalists of the Expedition.

*** The Volume may also be had in Three separate Sections, forming PARTS XXXI. to XXXIII. of the entire Work, as below:—
XXXI. "Report on the Keratosa," by N. POLEJAEFF, M.A. Price 6s.
XXXII. "Report on the Crinoidea—The Stalked Crinoids," by P. H. CARPENTER, M.A., D.Sc. Price 5s.
XXXIII. "Report on the Isopoda—The Genus Serolis," by F. E. BEDDARD, M.A., F.R.S.E., &c. Price 6s.

Printed for H.M. Stationery Office: Published by Order of H.M. Government: sold by Longmans & Co., John Murray, Macmillan & Co., Simpkin & Co., Trübner & Co., E. Stanford, J. D. Potter, and Kegan Paul & Co., London; A. & C. Black and Douglas & Foulis, Edinburgh; and by A. Thom & Co. and Hodges, Figgis, and Co., Dublin.

TEXT-BOOKS OF SCIENCE.

PRACTICAL PHYSICS.

By R. T. GLAZEBROOK, M.A., and W. N. SHAW, M.A., Demonstrators at the Cavendish Laboratory, Cambridge, with 62 Woodcuts.

Fcap. 8vo. Price 6s.

"Here is a work that has really been much wanted by students and teachers engaged in physical laboratories. . . . So far as we know there is no similar work in existence. . . . Teachers will find the volume of special value to them; while students, particularly those who have not a demonstrator to appeal to, will find many of their difficulties removed by a careful perusal of its pages."—*English Mechanic.*

London: LONGMANS, GREEN & CO.

SECOND EDITION, now ready at all Libraries and Booksellers'. One Volume, Demy 8vo, with Two Maps and numerous Full-page and smaller Woodcut Illustrations. Price One Guinea.

THROUGH MASAI LAND:

A Journey of Exploration among the Snowclad Volcanic Mountains and Strange Tribes of Eastern Equatorial Africa.

Being the Narrative of the Royal Geographical Society's Expedition to Mount Kenia and Lake Victoria Nyanza, 1883-1884.

By JOSEPH THOMSON, F.R.G.S., Leader of the Expedition, Author of "To the Central African Lakes and Back."

From the *Times*.—"It would indeed be difficult to find another man who could have given through what Mr. Thomson has done, and have come out of it alive and with stainless hands. Mr. Thomson has been able to open up and shed broad daylight on a region previously absolutely unknown. . . . Altogether he has done a solid piece of work of unusual scientific value."

MUTUAL LIFE ASSURANCE.

SCOTTISH PROVIDENT INSTITUTION.

EDINBURGH—6, ST. ANDREW SQUARE. LONDON OFFICE—17, KING WILLIAM STREET, E.C.

The ATTENTION of ASSURERS is directed to the SPECIAL ADVANTAGES obtainable in this Society, in respect of ECONOMY—EQUITY—SAFETY.

ECONOMY.—The Premiums are, in many cases, 20 to 25 per cent. under the usual rates, so that a Policy for £1250 may generally be had for the yearly payment which would elsewhere assure £1000 only.

EQUITY.—The whole Surplus is divisible among the Policy-holders themselves, on an equitable principle—no share being given to those by whose early death there is a loss to the other Members. From this source large additions have been made, and may be expected in the future.

SAFETY.—The Business (which for ten years has exceeded a Million yearly) is of the most select character, and conducted at the smallest cost.

The expenses, which are less than in any Office transacting so large a business, were last year under 9 per cent. of the net Premiums, and little over 6 per cent. of the year's Income.

THE FUNDS accumulated from Premiums exceed **£5,000,000**, the increase last year being **£333,383**.

Only two Offices in the Kingdom (both older) have as large a Fund.

Claims under Policies now payable a Month after Proof.

Reports, with Tables of Premiums, &c., on Application.

J. MUIR LEITCH, London Secretary. JAMES WATSON, Manager.

THE SNAKE-DANCE OF THE MOQUIS OF ARIZONA

The Snake-Dance of the Moquis of Arizona; being a Narrative of a Journey from Santa Fé, New Mexico, to the Villages of the Moqui Indians of Arizona, &c. By John G. Bourke, Captain Third U.S. Cavalry. (London: Sampson Low and Co., 1884.)

THE Pueblo Indians of New Mexico and Arizona have this general name from living in towns (Spanish *pueblo*, from Latin *populus*). Near a river, or oftener on the top of a steep-cliffed *mesa* or table-rock, may be seen these picturesque communal settlements, with their close rows of flat-roofed dwellings, walled with stone and mud, rising in terrace above terrace reached by wooden outside ladders, the whole forming a fortification strong enough to resist a sudden attack of the Apaches or Navajos of the plains, whose ravages in old times led the ancestors of the present Moqui, Zuñi, and other Pueblo tribes to resort to their peculiar architecture. Though these peoples were brought more or less under Spanish rule from the sixteenth century, and had to conform more or less to the Roman Catholic Church, the general barrenness and inaccessibility of their region saved them from being Europeanised to the obliteration of the native culture, like the nations of Mexico proper. In the Pueblos the archaic system of society, framed on maternal descent and exogamy, is still in full vigour, while the complex native religion seems almost as perfectly preserved as if the missionaries had never made the Indians wear silver crosses to their necklaces and march in procession to church on Corpus Christi. Thus it has come to pass that now, when the country has become United States territory, and the traveller bound for San Francisco passes close under the mud-walls of Laguna, there is made accessible to anthropologists a remarkable phase of barbaric society among a mild and intelligent people, where its study can be followed into the minutest detail. A few years ago, Mr. Cushing's papers in the *Century Magazine*, describing his life in Zuñi, excited wide interest. Now we have another instalment of Pueblo literature from Capt. Bourke, the officer selected by Gen. Sheridan to examine the manners and customs of the Indians of the South-Western Territories, and who in August 1881 went with a party to see one of the great rites of the Moqui religion, never before witnessed by a white man.

On his way to the Moqui towns, Capt. Bourke paid a visit to the Pueblo of Santo Domingo. Here the Indians profess to be Catholics, but (as the cura of the parish last year admitted to the writer of the present notice) they keep their old religion too. This comes out in the description of the festival Capt. Bourke's party were present at, where the procession-dance was performed by men with bodies painted pink and white, and wearing only the cotton kilt of their forefathers, while the women's headdresses were thin wooden tablets of Zuñi make, cut in the step-pattern which in Pueblo art conventionally represents the rain-clouds, for the coming of which to fertilise their arid country the ceremonies of Pueblo religion are one unceasing prayer. The clowns had the same prominent position as in the Zuñi dances sketched by Cushing; naked all but the old Mexican *maxtli* around their loins, and painted all over in black and white stripes, with tortoise-shells rattling at their knees, and their hair tied in with corn-shucks, they pranced hither and thither among the dancers. The whole purpose of the dance has been so far changed that it has become a procession bearing offerings to the shrine of St. Dominic, but even here the clowns are allowed their old licence, and chaff the Saint himself quite familiarly. There seem to have been more secret rites which the visitors were not allowed to see; indeed, when Capt. Bourke and Mr. Moran attempted to descend, note-book in hand, by the ladder through the sky-hole into one of the *estufas*—that is, the large cellar-chambers which serve as temples and council-houses—they were seized and ignominiously "fired out" by the yelling crowd below. A few days later, however, when they reached the rocky *mesa* on which stand the three Moqui Pueblos of Suchongnewy, Hualpi, and Hano or Tegua, to visit which was the object of their journey, Capt. Bourke found his way so well prepared by Mr. Cushing, that he was allowed the utmost liberty in examining everything connected with the snake dance, the great event around which all social and religious life naturally centred at the time.

A few days before, the young men had been out to the north, west, south, and east to collect snakes, and in one of the *estufas* Capt. Bourke found the whole catch stowed away in three great earthenware *ollas*. Next day the reptiles were to be seen turned out in a writhing mass, while two very old men lying on the ground were "herding" them: whenever a snake tried to wriggle away, they sat up, and with their eagle-feather wands gently brushed it till it turned back to the heap. These snakes were of several kinds, but mostly rattlesnakes, and youths came down the ladder from time to time bringing others, up to five feet long, wriggling in their hands. When the time approached for the ceremony, the visitors were politely got away to sit on a terrace-roof, where they could command a view of the procession, close to the sacred rock in the *plaza* or square, near which was planted in the ground a cottonwood sapling, apparently as a symbolic sacred tree; between the two stood a miniature conical lodge covered with buffalo hide, imitating in shape the *tepi* of the Sioux, and strongly suggesting a past time when the ancestors of the Pueblos may have lived as roving hunters on the prairie. The house-tops were crowded with women and naked children waiting for the procession. A noise of whirring and rattling, and there came forth from the arcade an old man sprinkling water on the ground, another carrying a basket of the sacred meal, men and boys with rattles, and another old man bearing a ceremonial bow, and whirling around his head a flat slip of wood fastened to a cord, in which we may recognise the "bull-roarer" known alike to the sacred rites of Australians, Kafirs, and ancient Greeks. Then came a party of dancers with their bodies painted green-black and faces blackened down to the upper lip and pipe-clayed below, with kilts of painted cotton, coyote-skins

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

[The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.]

The Relative Efficiency of War Ships

I HAVE a complaint to make against certain of the statements made in the article upon "The Relative Efficiency of War Ships," which appeared in your number for February 26. It is incorrect to declare that I advocated before the Committee on Naval Designs, in 1871, the system of construction upon which the ships of the *Admiral* class are built. The *Ajax*, *Agamemnon*, *Colossus*, and *Edinburgh* are designed upon a citadel system which I originally devised and advocated under certain limitations; but I deny, and always have denied, that any of those ships conformed to the fundamental and indispensable condition which I laid down as part of my system: viz. that the armoured citadel should be of ample dimensions to command the whole structure, keeping it afloat and upright, notwithstanding any amount of injury to the unarmoured ends. As this system has been violated in all the four ships above-mentioned, it is most unfair and improper to state that even those vessels are constructed upon a system which I advocated. But as regards the ships of the *Admiral* class they do not at all conform to the system which I advised, and the writer of the article in question could only have supposed them to do so from a serious misapprehension of the ships themselves. The article stated that the central part of all the ships in question, including the *Admiral* class, are "plated completely around with very thick armour, which extends from the upper deck to several feet below the water-line." This is a very incorrect description of the *Admiral* class, the armour in which does not rise to the upper deck at all, but is stopped in the form of a shallow belt rising but a foot or two, or possibly slightly more, above the water's surface. I repudiate with indignation the statement that such a system of construction as this, in association with the long unarmoured ends of the *Admiral* class, was ever recommended by me. For this reason I complain likewise of the statement in your article to the effect that my recent letter to the *Times* is but a continuation of the old and well-remembered *Inflexible* debate. So far is this from being so, that I distinctly pointed out in that letter that the cutting down of the armour to a mere belt of short length separated the ships of the *Admiral* class from the others, and imported "a new and terrible cause of danger." Another statement of which I complain, and which I desire to have corrected, is to the effect that I "refused to give evidence" before the *Inflexible* Committee. Were this true, it would constitute, in my judgment, a most serious ground of complaint against me, but it is not true. The *Inflexible* Report and its Appendices clearly exhibit the fact that within two days of the appointment of the Committee, and on the very day on which my evidence was asked for by the Committee, I handed in to that body a most elaborate mass of evidence, occupying no less than eighteen columns of the *Inflexible* Report, and illustrated by two sheets of drawings, this evidence setting forth in great detail my views of the subject, and the grounds of my dissatisfaction with such ships. It is true that four months later I was asked by telegram to attend the Committee, but asked to be excused on the ground that I objected to take part in the dilatory proceedings of the Committee, which I regarded as frustrating the objects with which it was demanded by Parliament. My full evidence was, however, already before the Committee, and had been for several

The above are the points of which I complain, and wish to have corrected. I do not ask as a matter of right, but I desire to have stated, that the long explanation which was given in the article in question for the purpose of showing that mere displacement is not, under all circumstances, a measure of the power of a ship, was, in my opinion, wholly unnecessary—at any rate, in so far as either Mr. Barnaby or myself was concerned. Both Mr. Barnaby and myself knew perfectly well that displacement is but a very rough measure of the power of ships, and no measure at all when ships of wholly different classes, and kinds, and dates, and systems are closely compared together. The only use that I made of the principle in my letter was to accept it for the moment as a rough basis of comparison between the ten latest French and the ten latest English ships, and I consider that for that purpose it was a good enough principle to indicate the inferiority of the English ships. But the acceptance of the principle for that purpose in no way precluded me from going further and showing that this rough comparison did not by any means bring to light other elements of grave inferiority, and even of danger, in the English vessels.

In the accompanying diagram the great difference between the *Inflexible* or *Agamemnon* class and the ships of the *Admiral* class is clearly illustrated. In both figures that part of the armour which is above the water is shown in full black, the part below the water being indicated by dotted lines. A glance at the diagram is sufficient to make it readily understood that the

Agamemnon, whose side armour rises several feet above the water, can be inclined to a considerable angle before her armour is brought under the water, whereas a very slight inclination only is necessary to bring the extremely shallow armour of the *Collingwood* under the water. In the case of the *Agamemnon*, therefore, the armour she possesses affords her a considerable amount of resistance to capsizing, while the resistance thereto derived by the *Collingwood* from her armour is almost *nil*. The same remark applies, of course, to the buoyancy of the armoured out-of-water parts of the two ships, the *Collingwood* having but a small fractional part of that which the *Agamemnon* possesses.

E. J. REED

[We give insertion to this communication from Sir Edward Reed with great pleasure, because one of the chief objects we sought in our article was to support his view that the stability of the ships of the *Admiral* class under the conditions which might be expected to occur in a naval engagement was open to grave question, and to reassert that further scientific experiments should be made.

We regret that the fundamental difference, so far as *fighting* stability is concerned, between ships of the *Inflexible* and *Admiral* type, which is now brought out so well by Sir E. J. Reed's diagrams, was not emphasized in the article so strongly as it should have been.—ED.]

st Presents Itself among the Phenomena of Nature

r of the 5th you give a short abstract of a recent Royal Institution by Mr. G. Johnstone Stoney, on How Thought presents itself among the Phenoe." In this abstract I observe an assertion which to me, and, I must add, quite unintelligible. It irst paragraph. The assertion seems to be that solute distinction between molar and molecular such as that, in the case of molecular motion there ty for the conviction that there must be some e moved. The conception of motion involves the matter as a necessary or inseparable concomitant—abstract idea of motion may, in a sense, be separated. Is there any difference in this respect between olecular motion? A molecule is a group of atoms, n is only conceivable as an ultimate particle of ue that some further explanation may be given upon uch is one of the highest interest and importance, ter of physical and of metaphysical speculation.

ound Vision and Morphology of the Eye in Insects

NEY HICKSON, in your issue of February 12 (p. 341), in statements concerning my paper in the *Transe* Linnean Society on this subject. I will not follow through his entire article, as I conceive it is sufficed by my paper itself. He says: "It would be ring evidence of this kind to confirm a theory which lly established." I would ask Mr. Hickson if anydain the vision of the compound eye intelligibly on theory? I would also remind your readers that ey, writing of the crayfish in 1880, accepted the view ne caution; he said, "The exact mode of connection fibres with the visual rods is not certainly made out;" rede never accepted it, and Max Schultze admitted were grave physical difficulties in the way of its

kson is very anxious, apparently, to deny me what I ned—*i.e.* the discovery of a layer of definite structure e basilar membrane. What I do claim is the dishe nature of its elements. I deny, in my paper, that erve passes through these structures, and I deny that ist of a fine reticulum of nerve-fibres. These are of fact and observation, not of theory or deduction. rong, I am wrong. But the way to test my work is by out the eye as I have worked it out. I have spent years in this work, and I do not expect to have my erally accepted for another ten years.

bsence of pigment and retinal purple is a secondary

I do not know, nor does any one know, whether retinal purple or not in this layer. I admit that pigabsent in the retina (my retina) of some insects and ns, and I have recorded the fact. I am not yet conut we can say vision is impossible without it. Albinos on undoubtedly in the absence of retinal pigment. He a bold man who asserted that vision could not be without pigment in the retinal region. The colourless a film of the photographer is affected; why not retinal Here, again, it is a question of fact, not theory.

resence of pigment proves nothing with regard to the of the great gods, any more than it shows that the iris tebrate is sensitive to light.

bsence of any retinal layer in Periplaneta and Nepa is ly on the part of my critic, for I have examined it careboth, and I figure the elements from the former. I a that the same structures exist in all the crustacea, h they are short and more difficult to demonstrate.

n, in the morphological question my views are not fairly by Mr. Hickson. I admit his facts, but deny his deduc. The hypodermis forms the dioptric structures, as the ds of the vertebrate forms the lens; my contention is e retina in the insect, like the same structure in the Vertee developed as an outgrowth from the nervous system.

BENJAMIN THOMPSON LOWNE.

Cambridge Gardens, Notting Hill, W., February 23

I DO not wish to undertake a lengthy controversy with Mr. Lowne on the question of the retina of insects, but I cannot refrain from making a few remarks on the letter you publish above.

I am afraid Mr. Lowne has misunderstood my criticism when he asks me "If any one can explain the vision of the compound eye intelligibly on the received theory?" My criticism was not meant for any theory of pure optics, but for the theory that the retinulæ are not the true nerve-end cells.

Mr. Lowne's statement that albinos are devoid of retinal pigment is not strictly accurate, for Kühne pointed out, and any one can see for himself, that all albino rabbits and other vertebrates possess a true retina purple. Moreover, the rods of Cephalopods and of Pecten, which seem to be devoid of pigment in spirit specimens, possess, as Hensen has pointed out, a true retina purple. In fact, I know of no exception to the rule I laid down—namely, that optic nerve-end cells are pigmented, and I should be glad if any of your readers could point out any exceptions to it.

Mr. Lowne's reiterated statement that the optic nerve fibrils do not end in the retinulæ is, as I said, contrary to my own observations. I have submitted my preparations to several eminent naturalists, who agree with me in my account of their distribution. I shall be happy to submit them to any others who may feel interested in this matter.

The other statements in my notice which Mr. Lowne controverts I will not refer to again here, as they will be fully explained and illustrated in my forthcoming paper in the *Quarterly Journal of Microscopical Science*, the proof-sheets of which I have now in hand. SYDNEY J. HICKSON

Civilisation and Eyesight

IN connection with Lord Rayleigh's letter in NATURE, p. 340, on the above subject, I venture to hope that the following may be of interest:—

In the "Expression of the Emotions" the late Mr. Darwin quotes some observations—if I recollect correctly—by Gratiolet tending to show that, under the influence of *fear*, the pupils of animals' eyes dilate. Observations extending over some years have convinced me that fear is undoubtedly capable of thus causing dilation of the pupils (see Dr. Hack Tuke, "Influence of the Mind on the Body"); and in general literature, such as travels, novels, &c., I have met with many instances in which the eyes of both men and animals under this condition have been so described by the writers.

Is dilation of the pupil under the influence of fear to be explained on the assumption that the increased aperture of the eye enables a more effective scrutiny of the object causing terror, and has thus been of service in the struggle for existence?

An answer to this question is not easy to give, for, although dilation of the pupil under the influence of fear may have originally been of direct service to an animal, yet this condition may in time have come to be associated with other emotions in which it is not so easy to trace any such direct benefit.

Observations upon the subject are by no means easy (varying light, for instance, varies the aperture of the eye), but in the course of my observations I became much inclined to believe that other strong mental emotions besides fear (*e.g.*, joy or pleasure) may be capable of giving rise to dilated pupils.

Charlotte Brontë, in "Jane Eyre," is one of the only writers who associates a dilated pupil with other emotions than fear. Here is the sentence:—"Pain, shame, ire, impatience, disgust, detestation, seemed momentarily to hold a quivering conflict in the *large pupil dilating* under his stern brow."

It is to be feared that the experimental investigation of eyesight with artificially contracted or dilated pupils is scarcely practicable, for drugs, such as atropine or eserine, act not only on the pupil, but also on the power of accommodation for distance. J. W. CLARK

Liverpool, *February* 21

P.S.—I see Dr. M. Foster, in his "Text-Book of Physiology," mentions the dilation or contraction of the pupil which attends the adjustment of the eye for distant or near objects respectively, and also its dilation "as an effect of emotions." It thus seems highly probable that strong and very different mental emotions may give rise to dilated pupil. Dr. Herdman has suggested to me, as an explanation of this, that an intens

excitation of one brain centre may possibly act in the same way as a direct inhibitory impulse by partially paralysing an adjacent centre.

The Forms of Leaves

THERE are several points in Sir John Lubbock's lecture (NATURE, February 26, p. 398) which seem to invite some little criticism. That "the size of the leaf . . . is regulated mainly with reference to the thickness of the stem" seems somewhat self-evident, as a large leaf must have a large stem to carry it, as, *e.g.*, may be seen by comparing the slender shoot of a Deodar with a cabbage-stalk; but he adds: "The size once determined exercises much influence on the form." This is a *deduction* which seems to require *verification*. Sir John gives the area of a beech-leaf as about 3 square inches, but the form remains the same whatever the size. Size rather depends on vigorous growth, as in the following instances: *Populus alba* leaves on a vigorous basal shoot were $6\frac{1}{4} \times 3\frac{1}{2}$ inches, the diameter of the shoot being $\frac{1}{8}$ inch; on the upper branches of the same tree many leaves were only $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, the diameter of the shoot being also $\frac{1}{8}$ inch. Similarly growing oak leaves of the same shape were 6×3 inches and $2 \times \frac{3}{4}$ inches respectively. An *Aucuba japonica* bore rounded leaves on a basal shoot $4 \times 3\frac{1}{2}$ inches, but those on the stem were 4×1 inch. In this case, as in other plants with (normally) dimorphic leaves, as ivy, it is difficult to see what connection there is between size and form. Indeed leaves of every degree of superficial area can be found amongst the lobed ones on the climbing stem of ivy, and the entire ones of the flowering branch. Sir John adds that "the form of the inner edge [of the beech] . . . decides that of the outer one." He does not seem to have verified this deduction. The two edges are symmetrical in this leaf, but they are not so in the elm and lime. How will the inner edge explain the cause of their obliquity? If, however, the *buds* of the lime be examined, a more probable cause (as it seems to me) will be discovered in the conditions of development. He describes the *Eucalyptus*, when young, as having "horizontal leaves, which in older ones are replaced by scimitar-shaped phyllodes." Bentham and Hooker say of *Eucalyptus:* "Folia in arbore juniore sæpe opposita, in adulto pleraque alterna," but makes no mention of phyllodes. Speaking of evergreen leaves, he says: "Glossy leaves have a tendency to throw [snow] off, and thus escape, hence evergreen leaves are very generally smooth and glossy." This sentence appears to imply that such leaves are glossy in anticipation of snow! a deduction which certainly requires verification. Again: "Evergreen leaves often have special protection . . . by thorns and spines. Of this the holly is a familiar illustration; and it was pointed out that in old plants above the range of browsing quadrupeds, the leaves tend to lose their spines and become unarmed." The inference the reader draws from this is that when the holly grows out of reach of browsing animals it has no necessity to produce prickly leaves, and so changes them accordingly, thereby implying that unarmed leaves were in some way preferable. This is another instance of deductive reasoning which requires verification, for it seems to be attributing to the holly a very unexpected process of ratiocination! But it is not at all usual for hollies to do this. I have several from six to nearly twenty feet high, and not one has borne an unarmed leaf. Though my cows do not touch a holly hedge, yet one young bush lately planted has taken their fancy, and they have bitten it all to pieces. On the other hand one bush (in the garden), a variety with unarmed foliage, occasionally throws out a branch with prickly leaves, though the cows are not admitted where it grows.

"Fleshy leaves were principally found in hot and dry countries, where this peculiarity [*sic*] had the advantage of offering a smaller surface, and therefore exposing the plant less to the loss of water by evaporation." Surely the usual explanation, that it is the thick cuticle which prevents rapid exhalation is a better reason than Sir John's deduction from the small size of the leaves? Speaking of aquatic plants, he says that the submerged "cut up" leaves of such plants presents a greater extent of surface;" and adds that "such leaves would be unable to support even their own weight, much less to resist any force, such as that of the wind.." I should be glad to know if he has verified the first statement by actual measurements; for an *à priori* assumption leads one to fancy that a complete leaf would have a greater surface than one represented by its ribs and veins only. With regard to the second and third statements a "natural experiment" completely refutes his deduction. I know a place where a small pond dried up last summer, and a large portion of the ground was covered with a dense moss-carpet, composed of the *erect* filiform branchlets of the "aquatic" leaves of *Ranunculus aquatilis*, which had become modified to their new medium, and perfectly adapted to enjoy its new existence.

In offering these few criticisms for Sir John Lubbock's consideration, I would venture to remark that he seems to have followed too closely in the deductive methods of another writer on leaves, and which called forth the following remarks from Prof. Lankester:—[He] "gives us hypotheses, supported by insufficient evidence, and deductions from the generalities of Evolution, but he is relatively deficient in 'verification.'" (NATURE, vol. xxviii. p. 171). GEORGE HENSLOW

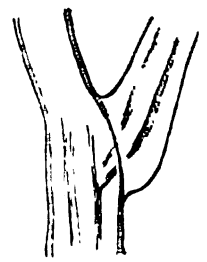
The Fall of Autumnal Foliage

MR. FRASER alludes to "the unpursued inquiry as to the cause of leaves falling in autumn" (NATURE, February 26, p. 388), and I do not find it mentioned in Sach's "Text-book," but Dr. Masters, in Henfrey's "Elementary Course of Botany," fourth edition, p. 515, speaks of "a layer of thin-walled cells being formed across the petiole," but does not say when the layer is derived. Duchartre, however, gives a pretty full account of opinions up to 1877 ("El. de Bot.," deux. éd. p. 441), which reduces to two, viz. Schacht's, who attributes it to a growth of periderm, and that of Mohls, who recognises a special layer which he calls *couche séparatrice*, considering the peridermic layer to be often, but not always formed. Subsequently, M. Lavialle



examined different plants and corroborated Schacht in regarding the periderm as the *cause prédisposante*, and cold to be the *cause efficiente*, which contracts "le tissu de la base du pétiole, spongieux, aéré, élastique à un degré beaucoup plus considérable que celui du coussinet." From my own observations on the horse-chestnut, ash, &c., it appears to be in these cases a continuation of periderm produced by the phelloges of the bud, which invades the base of the petiole, till it meets in the axil, cutting right through the fibro-vascular bundles of the petiole. As this suberous layer dies, the leaf necessarily falls off. As long as a leaf is in vigorous health it would seem to resist invasion, and last longer, as do evergreens. I inclose a section I possess of a slide showing the process in the horse-chestnut.

Forest-Trees in Orkney

IN NATURE of February 26 (p. 388) Mr. A. T. Fraser states that "a peculiarity of Caithness and the Orkney and Shetland Islands is that no forest-trees can be got to grow," and proceeds to explain this by the preponderance of polarised light. As far, at least, as Orkney is concerned, I am prepared to deny this calumny. It is true that forest-trees are not the characteristic feature of the Islands, but they do occur. At Binscarth, between Kirkwall and Stromness, there are willow, ash, sycamore and Scotch fir. They require to be protected—from the wind, I presume, and not from the light—by hedges of bour-tree (*Viburnum*). In the street at Kirkwall itself there is a fair-sized sycamore.

Trinity College, Cambridge JAMES CRAIG

YOUR Indian correspondent, Mr. A. T. Fraser, can scarcely be acquainted with the primitive jungles of Southern India, or he would have observed that there, at one and the same time, the aspect of all the four seasons is displayed in the vege-

, in two different years, during the months of ruary, we not unfrequently drove up to Mercara, stance of ten miles from the place where we were e way thither we saw some trees in their winter perfectly bare branches, others had the tender , some again were in all their summer glory, and ed with the most brilliant autumnal tints; this ibly due to the great variety in the species of trict. GEOFFREY NEVILL

to announce the comparatively early death r. G. Nevill, which took place at Davos Platz, and lingering illness, on February 10. This m among us another of the scanty band of achologists, whose ranks, only a few days ered a similar loss in Mr. J. Gwyn Jeffreys. s labours have been principally confined to e he was for many years one of the assistant-ents under Dr. J. Anderson in the Indian alcutta; his work is, therefore, better known o have collected in the East and written on an fauna of that part of the world. For many as a constant correspondent and colleague of , who can testify to the large and varied know-Nevill possessed of the different forms. A number of species were sent him by Mr. Nevill o-time, many of which still remain to be de-Mr. Nevill was the author of many papers on te study, most of which are to be found in the f the Asiatic Society of Bengal; but perhaps nd most useful work, particularly to those in distribution, was the "Hand List of Mol-he Indian Museum" (Part I. comprising the a and Prosobranchia-Neurobranchia published ber, 1878, and is remarkable for the accuracy h the localities of the different species is given, ollections from whence they were received. He logued the Ampullariacea and Valvatidæ and ae). Unfortunately, the whole catalogue of the ds is incomplete, for his health failed him alto-18th. Yet he struggled on to the last with his n when unable to leave his room to go as his office in the Museum, and was compelled y to give up his appointment and return to The entire arrangement of the Mollusca in the eum formed a part of his work when there, and ll and admirably done. Almost his last work in was at Mentone, in 1878-79, where, in the poss-beds, he made a careful collection of the shells, ly the smaller species, a list of which he pub-the Zoological Society's *Proceedings*. Yet even as last summer, when hardly able to move from s and partial paralysis, he was getting together -shells to be obtained in the country around the Como.

ey Nevill was born at Holloway on October 5, he was the second son of Mr. Wm. Nevill, who resided for many years at Langham Cottage, ing, a gentleman who made mineralogy his and whose collection of meteorites was well As is often the case, his son inherited kindred for, when quite a boy, his attention was directed to llecting both in Germany and in England. Most of the English species in the Calcutta Museum originally formed a part of this collection, and bear labels from near his early home at Godalming. He received his education at Dr. H. D. Heatley's school at Brighton, and afterwards spent some time at Bonn in the house of Dr. F. H. Troschel, Professor of Zoology, and this no doubt confirmed his early taste for natural history and directed his future career.

He was never strong, so, after entering into mercantile life in his father's house, and his health breaking down, he was ordered abroad, and he proceeded to the Cape, the Mauritius, and Bourbon, where he collected largely, and formed a valuable and rich collection. Some of the results were described in joint papers by himself and his brother, Hugh Nevill, of the Ceylon Civil Service. He went on to the Seychelles Islands in 1868, where he remained some time, still further enriching his collection, and then went on to Calcutta. At this time an appointment offered itself in the New Museum, which he took and filled for many years. Here in Calcutta during this period a little band of workers in conchology were drawn together, most of whom were employed on the different surveys of the country. Season after season, on return from the field, the results of their labours in every part of India accumulated and were examined. Ferd. Stoliczka, one of the first to be removed, was one of the most ardent workers, and all benefited from his deep, more advanced knowledge of the subject.

The survivors will recall those pleasant intellectual gatherings when they hear of Geoffrey Nevill's death, and future students and collectors of Indian Molluscs will appreciate the work he lived to perform, and which will render their work in the galleries of the museum in Calcutta more easy.

REPORT OF THE COMMISSIONER OF EDUCATION IN THE UNITED STATES FOR THE YEAR 1882-83[1]

IT is impossible to read the account which the United States Bureau of Education, in the opening pages of this Report for 1882-83, gives of itself and of its labours, without being convinced of the value of the matter therein contained. A total of over 10,000 institutions of education of various kinds are in correspondence with, and supply information to, the department. An idea of the work also which falls to it may be formed from the fact that some questions addressed to it have necessitated months of research by several clerks, while the labour which its publications have entailed, as well as the value placed upon them, are shown by the fact that one of them was *asked for* by 10,000 persons of different addresses. Since all is voluntary, the Bureau claims to work the most complete system of the kind in existence. The wide compass of its survey is indicated by the very full account given, among other foreign intelligence, of the Report of the English Commission on Technical Education. Besides itself circulating through the world 20,000 copies of its Report, the office is require dto print 18,000 copies more for the use of, and distribution by, other members of the Government. Its library—where all the items of information which it is possible to collect, down to cuttings from newspapers, are gathered together and classified—is an immense work; and we can well believe that, "if this office were put in possession of a small sum annually for the purpose, it would make effective and useful displays at exhibitions, of American education ... the most unique feature of our national life."

The report of this education generally is far more satisfactory than in other years. There has been a general increase, first in the number of scholars, even in Maine where the population has become smaller, and in New Jersey, New Hampshire, Connecticut, South Carolina,

[1] Washington Government Printing Office, 1884.

and Kansas, where schools have become fewer. Though the contrary might have been expected in an increasing country, a great complaint of the Report is the multitude of small schools which require consolidating for the sake of employing better teachers and apparatus. The suggestion is made that each State should fix a minimum of salary to be paid to any teacher; this not only must be good for the children, but would of itself urge forward the consolidation, where distance allowed it, of small schools of less than ten or twelve scholars.

In Rhode Island, and in city schools generally, the competition of factories is lamented. The deficient average attendance is imputed to the demand for cheap labour; and obligatory laws are quoted, among other things, as an antidote. It should not be forgotten that the inexorable enforcement of those laws is what is in reality the greatest kindness to poor families; for if the cheap labour of young untaught children once enters the market in the smallest quantities, it becomes impossible to gain a fair price for the work of those older and better taught. But, protected from all such unfair competition, the child's education becomes a common necessity. No doubt the difficulty is much felt in Alabama, North Carolina, Louisiana, and Mississippi, the only States whose reports are generally unsatisfactory: States where negro labour keeps down the wages of white children.

There has been an increase, again, in the number of teachers: with regard to which it is interesting to note that in three States the number of men has fallen off, while in them, and even in frontier States, that of women has increased; and an increase also in the item of teachers' salaries; even in Illinois with fewer of them, in Indiana, where the population has decreased, and in Michigan, where in past years the amount had fallen off.

The variation in different States of the expenditure on education, however, is still exemplified in the fact that Massachusetts pays fifteen times the amount per head that Alabama pays!

The educationists of Kentucky, where whites and blacks are treated alike with regard to schooling, appeal to the Peabody Trustees for advice to the Legislature. This latter body, who are gaining an influence like that of our Charity Commission, have concentrated their money upon training teachers, with successful effect over school work in the south. Another benefactor has bequeathed over 700,000 dollars to the whites of New Orleans for educational purposes.

The improvement in the organisation of systems, the greater efficiency of work, and the deeper interest felt by the people, is indicated by the public schools in some States superseding the private ones; and Gen. Eaton attributes to the influence of the superintendents (officers whom we have before quoted as combining the knowledge of our inspector with the zeal of our chairman of School Board) the two most promising general movements now going on, viz. the increase of local taxes for education in the Southern States, and the effort to abolish small independent, irresponsible districts in the older Northern States.

Still, nothing can be more depressing than that, in a community naturally the leading people of the world, a sober report of a patriotic commissioner should still find it necessary to say more than once in his Report, that a work so all-important to the future of that community as education should be marred by school commissioners persisting to license the cheapest teachers they can procure, and using the license as a means of favouring relations, political supporters, and such like; thus rendering useless the efforts of examining bodies, who have pointed out the really competent persons for this most responsible office.

We have no need to enlarge again here upon the United States difficulty, the education of the negro. The burning question of course is, Who is to pay for it? The Report speaks confidently of securing national aid, the need of which has been so strongly urged before. One gentleman gave 1,000,000 dollars towards the work. The religious denominations have so far been the great supporters of black education.

We, in England, can better enter into the labours of those who are trying to raise the street Arabs to a generally higher level. Few things ought so much to cure anxious reformers how little their improvements depend upon the form of government, as to see how the struggle of the poorest for existence is as sharp and demoralising in the large towns of the United States as it is in England. One of the leaders of the Kindergarten system has laid down that "the best energies of the faithful teacher are often required when the work of the schoolroom is over. There is much visitation to be done to look up absent children, and, where sickness invades, the teacher is often called upon to supply medical aid and other necessary help; and, where death ensues, there is sometimes need but the Kindergarten helpers to see the little ones decently buried;" and, in fact, not only to take all the duties and responsibilities off the hands of parents, but to provide an antidote to their mischievous example as teaching. Their success in many cases must lend supporters on to the venerable yet now radical proposition, which will be most offensive to Mr. Herbert Spencer, that education from infancy should be the care of the State; and, strange as such a suggestion may seem among English homes, it is very much in harmony with modern division of labour which makes the parent less able to educate, in the full meaning of the word, his family, and the professional Kindergartens so much the more so. And the same principle is to be traced in the recommendation that homes, as well as training-schools, should be found for nurses.

Both in primary and secondary schools witness is borne to the improved teaching. The importance to the formation of the example of good teaching to be found in the normal schools, as well as the precept on the subject, is insisted upon; a difficulty often met with being the want of correcting bad teaching in the lower schools. We see, on the other hand, the multiplication of teachers well trained in public normal schools is, as we have said, cited as the surest, and, in the long run, the most economical means of raising the standard of education throughout the country.

Examinations like our Oxford and Cambridge Locals, held by the regents of New York, are leading to great uniformity in the teaching of the second-grade schools.

Perhaps the most striking thing in the Report is the important part which women are now taking in study as well as in teaching, in the United States. The demand and attractiveness of commercial life to the young men of America, with the energy and self-reliance of its women, are leading to the result that the latter are becoming a learned class there. We have already remarked upon the large and increasing proportion of female teachers in the elementary schools. But, moreover, while twice the number of women begin a high school course, three times as many women as men complete the fourth year. Although the increase is not large this year, there are over 4,000 women in institutions of superior instruction. At Purdue University, where practical mechanics is taught, a number of young ladies have been among the special students and "have done the same work as the young men, and though progressing much slower, have been nearly as successful." Educated women are now also the leaders of many philanthropic movements.

The education of the blind and the feeble-minded urged as a matter of public economy, their cost if left uncared for amounting to much more. The same considerations have many times been urged in favour of such schools. But they are all attempts to counteract human nature that all these diseased specimens shall be trans-

ibly extirpated, and it is hard to see a satisfactory result of these efforts in the long run. A singular mischief has recently been commented upon by Prof. Graham Bell (see NATURE, No. 795), arising from the system of teaching deaf-mutes a language and literature, intelligible among themselves, but not familiar to the general public. Hence they prefer their own society, and are trying to form deaf-mute settlements which must result in hereditary transmission to the whole community of this terrible degeneracy. It will be a curious experiment if allowed to take its course.

A most healthy sign of the times is that the increase of students at the schools of science is far larger than the increase in the number of establishments. It shows a general appreciation of their work, and in an enterprising country like America will soon bring about an increase in the number of schools. Institutions are becoming more general which undertake to train students for the higher schools of science. The cost of laboratories and apparatus and the scarcity of teachers are two of their difficulties, indicating at the same time the high standard of work they aim at. We note with pleasure that the sole purpose of the Wisconsin Agricultural Experiment Station is the discovery of new truths and laws which may be of benefit to agriculture, and farming is taught there as a scientific pursuit. In the Storrs Agricultural School at Mansfield, Conn., though of less ambitious character, students receive instruction both in the class-room and on the farm. In the class-room they study those branches of natural science which have a directly useful bearing on New England farming, such as general and agricultural chemistry, natural philosophy, farm mechanics, surveying, botany, zoology, geology, animal physiology, mineralogy, and theoretical agriculture, stock-breeding, and composition. The general principles of these sciences are taken up first, and afterwards their special applications to practical agriculture, which includes the improvement of the soil by tillage, draining, manuring, and irrigation; the culture and handling of the various field, garden, and orchard crops of New England—grass, grain, roots, vegetables, and fruits—from planting to market; the use, care, and repair of farming tools, implements, and machines; the breeding, rearing, training, and feeding and use of live stock; the best methods of dairying, the business and management of the farm in all its details. . . . The intellect being called into play, farm work is divested of its monotony and robbed of the repressive influence derived from it when viewed as mere physical labour."

It is well urged in favour of an institution like the St. Louis Manual Training School, that through the minute division of labour which necessarily attends our increased machinery, the old method of teaching a trade is rapidly and inevitably disappearing; that it is only at a technical school that the *toute ensemble* of a trade can be learned so as to be intelligently carried on and fresh inventions led to; that there is an idea afloat that it requires no education to be a mechanic, and hence the despising of both craft and craftsman, whereas the thorough understanding of both theory and practice of a skilled industry makes its owner "the peer of the statesman; and from the union of his head- and hand-work come a large part of the civilising agencies of the nineteenth century."

The English Commissioner on Technical Education reports on the efficiency of the American workman, which is mainly attributed, by all who have inquired into the subject, to the primary education acquired, by them during a prolonged attendance at school, and now the idea is to be traced through all the Report upon the subject, that to each the pupil his trade should henceforth be the work of a school; as much one part of education as the three R's the other part.

And not the work of a primary school only, but it is even urged that it should be the work of the Universities to send forth young men, fitted by technical training to lead in the development of the State; its fields, mines, quarries; its railroads and water-power; its manufactures and commerce." And already at Cornell University, as well as at Massachusetts Institute of Technology, electrical engineering is taught sufficiently extensive to prepare a man for ordinary electric work or advanced study. To Terre Haute, Ind., a small town of 26,000 inhabitants, the splendid legacy of a property bringing in 25,000 dollars a year was left for a technical school, in the starting of which great care as well as energy have been shown.

Very different, however, from these buoyant views is the record to be found also in this Report, that in Austria the higher schools for technical instruction have been decreasing for the last few years.

Nor again is science only, but art also in its more marketable shapes is becoming rapidly the work of schools. A public art school, under the direction of Mr. C. G. Leland, has been trying an experiment as to what children, nine-tenths of them from thirteen to fifteen years of age, could do in the way of art manufactures by being taught designing and art processes. Besides developing inborn talent, this school not only finds a commercial value in their productions, but insists upon what is becoming generally observed, that technical teaching, though shortening school hours for other work, by no means reduces the amount of progress made in the latter, brighter wit and interest being excited by hand-work at intervals with head-work. Elsewhere in the Report a protest is quoted from Harvard University which will be re-echoed from the breast of many an English *paterfamilias*, against athletic sports being made too much a business or profession, instead of a recreation. Besides the waste of time which, it is urged, might be given to other things, such a standard of excellence as the few attain makes the game very exclusive and confined to a small number. Of course we know the reply often made to this, viz. that the best players are also the best workers; but do not these simultaneous experiences strongly suggest that some technical art might take the place of a dangerous game, thus infusing intelligence into the former, and providing the student with a means of competency in case of reverses? Many arts are more intellectual and less laborious than football or agriculture as carried on at Rugby, England, or Rugby, Tennessee.

The unsatisfactory condition of the medical profession in the United States, which has been remarked upon in previous reports, is in this one traced back to the thinness of population a century ago; a population also of vigorous physique occupied in clearing and settling an enormous territory, and free from most of the diseases that afflict humanity of lower vitality, and under less favourable circumstances. The early colonial physician often combined other functions with those of healing: sometimes he was a minister of the Gospel, sometimes a farmer, a shopkeeper, or a mechanic. The bulk of the profession at the beginning of the century, and for many years afterwards, did not possess any medical degree. The result followed that men of natural boldness revolted against the frequent ignorance and numerous errors of such physicians, and became followers and advocates of special medical doctrines, and supported the "botanic" school of practice, that of Hahnemann—hydropathy, physiopathy, vitopathy, electropathy, or other "medical heresies." Degrees have been too easily obtainable through numerous schools competing for popularity, and offering them for little money and less work, with the natural result of their being little valued. The Report, therefore, after going largely into the subject, and deprecating the present state of things, urges fewer schools and higher degrees, which will be worth jealously guarding, to be given by State-appointed examiners only, on the attainment of a much higher standard. Since we are told that ten colleges have agreed upon a uniform entrance examination to the great help of masters pre-

paring boys for their studies, it may be hoped that a more general union may be arrived at with regard to this standard.

Free libraries are still progressing, and so interesting are the statistics of these "universities of the people" in the United States, that Gen. Eaton promises a special publication on the subject, reprinting such parts of the great Report of 1877 as have permanent value. Several magnificent bequests and donations of books to large libraries show how naturally large private collections will gravitate to the free public library, where the locality is happily provided with one. One such, that of Dr. Toner's, containing 27,000 books and 12,000 pamphlets, was thus bequeathed to the Library of Congress. This latter institution, at the end of 1882, already contained 480,076 volumes and 160,000 pamphlets, and the forthcoming plan of a new building to keep in utilising order this rapidly growing mass is intended to embody the best appliances, arrangements, and ideas about library construction which such enormous accumulations render indispensable. An excellent precaution also against knowledge being locked up in over-large supplies of literature is taken at Chicago, where Dr. Poole, the great cataloguist, receives schools or teachers on a Saturday, surrounded by all the books of the library bearing upon some matter. By showing how interesting that subject is as a department of human thought and industry, and how much the contents of the library may help the student to a knowledge of such a subject, he has succeeded in producing a profound beneficial effect upon the upper grades of the school system. W. ODELL.

BIRDS BREEDING IN ANTS' NESTS

THE following communication to Mr. Grant Duff, Governor of Madras, has been forwarded to us for publication by Sir John Lubbock:—

To Major Awdry, Private Secretary to His Excellency the Governor of Madras

OOTY, *January* 18, 1885

SIR,—I beg to acknowledge your letter of yesterday's date.

The Southern Chestnut Woodpecker (*Micropternus gularis*), always, as far as I have observed, uses an ants' nest to nest in, and Mr. Gammie, the Superintendent of the Government Cinchona Estates at Mongphoo, near Darjeeling, has noticed the same thing with regard to the allied northern species, *Micropternus phaioceps*, and the peculiarity probably extends also to the allied species found in Burmah, Siam, &c.

Mr. Gammie thinks that when an ants' nest has been taken possession of by the bird that the ants desert the nest. This is a point on which I cannot speak with certainty. Mr. Gammie has taken nests of the northern species in which, although the bird had laid, the ants remained, and he has taken other nests where not a single ant remained; but there is nothing to show that these nests were not deserted before the bird took possession. I myself have taken nests of the southern form, in which, though the eggs were partially incubated, the ants remained, showing that some considerable time must have elapsed since the bird took possession. This is a point that I hope to be able to elucidate within the next few months, when the birds will be breeding.

When *Micropternus* is breeding the feathers of the head, tail, and primaries of the wings get covered with a viscid matter, having a strong resinous smell, and this substance is usually rather thickly studded with dead ants (*vide* "Stray Feathers," vol. vi. p. 145).

Two species of kingfishers also to my knowledge nidificate in ants' nests—viz. *Halcyon occipitalis*, confined to the Nicobar Islands, and *H. chloris*, which ranges from India as far south as Sumatra.

At Mergui, in South Tenasserim, I found a nest of *H. chloris* in a hornets' nest, and although I saw the birds repeatedly enter the hole they had made in the hornets' nest the hornets did not seem to mind it, but they resented in a very decided manner my attempt to interfere with the nest.

I am sorry I cannot give His Excellency more certain information as regards the desertion or otherwise of the ants from their nest after the birds have taken possession of it, but I hope to be able to finally settle the question shortly.

I am, Sir, yours obediently,
(Signed) WM. DAVISON

A NEW AMERICAN CLOCK

THE accompanying figure from *La Nature* illustrates a new American clock of ingenious construction. It is distinguished from all other clocks by the singular and original form of its pendulum; or rather of the system which serves to maintain a synchronism more or less perfect between the passage of time and the indications on the dial. The arrangement of this clock is based on

the principle of torsion. It has to be wound up daily, and the phase of the pendulum—that is to say, the time which elapses between two identical positions of the regulating system—is six seconds. The general mechanism does not differ from that of ordinary clocks; we find the main spring and other usual parts, and a train of wheels giving rotation to a vertical axis which is seen over the case and the rate of motion of which is to be regulated

echanism comes in. This vertical axis of bracket, P, to the extremity of which is l bead or ball, B, by means of a thread a few g. Putting out of view meantime the other the case, it will be seen that the axis, by the main spring, will turn with a rapid wing the ball B along with it. To regulate it is sought to interpose in its path suit- this is the object of the horizontal wire the hooks T, and of the vertical pillars fixed

The bracket P draws the thread in its l makes it strike against the arm T; it is and by virtue of its acquired speed, the ball aread around the pillar on the left; then winding of the thread and a rewinding in an ion, which enables the thread to pass the it in unwinding it strikes a second time illar, winds and unwinds anew, and only succeeds in passing this double obstacle after four successive windings, twice in one direction, and twice in the opposite direction around the same pillar. The thread thus set at liberty permits the bracket to turn 180° around the vertical axis. After this rotation it encounters two analogous objects placed on the right of the clock, and is delayed a certain time before passing these objects and returning to the pillar on the right. By suitably varying the length of the thread, which is easily done by means of a runner on the bracket, we obtain the complete phase of the movement with its eight successive windings of the thread, lasting exactly six seconds; and the clock is thus regulated, if not with all the precision of a chronometer, with an approximation said to be sufficient for ordinary use. The principle applied in this clock might possibly be utilised in cases where it is sought to regulate a slow movement of rotation by simple arrangements, both economical and uncumbrous.

CLOUD-GLOW APPARATUS

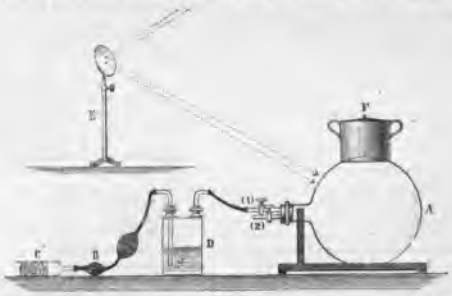
dness of Prof. J. Kiessling, of Hamburg, we te a simple and easily arranged piece of aich he has designed for the purpose of ex- an experimental scale some of the many mena which are produced when direct sun- tric light, penetrates a moist or a dry cloud. the apparatus can be used to produce on an xcited mist the same kinds of intense colora- were visible in such extraordinary brilliancy er 1883-84 during the hours of twilight at y place the whole world over.

wing pieces compose the apparatus:—

a globe, A, Fig. 1, holding about 20 litres, fixed in a wooden support, and closed by a rubber stopper bored with two holes. Through these holes enter two tubes of glass (1) and (2), with taps ground in.

2. An air-filter, C, consisting of a glass tube 30 centimetres long, filled with cotton-wool.

3. An India-rubber pump, B, for producing spray or mist. This is simply part of a common spray-apparatus, and is set so that it draws air from the air-filter and delivers it into the globe. By this means a pressure of one-sixth to one-fifth of an atmosphere is readily obtained. Suppose 15 or 20 grammes of water to have been introduced into the globe and such a pressure to have been produced, and then after about 10-15 seconds the other tap (2) to be suddenly opened, or removed quite out of the tube, the release of pressure will result in a sudden



g of the temperature, and the production of a y homogeneous mist, the density of which will on the quantity of aqueous vapour present.

simple heliostat, E, consisting of a mirror capable g turned either in altitude or azimuth on an iron and also of being clamped at any desired height.

Woulff's wash-bottle, D. This can be filled with ter so as to yield a supersaturated atmosphere; or, addition of ammonia or of hydrochloric acid, may vapours of these materials for experiment in the

cylindrical tin-ware vessel, F, with a spherical A, to be set upon the glass globe, to heat or cool it y be desired.

following experiments may be made with this atus:—

[1] *The Ordinary Lunar Halo.* First cover the surface of the mirror with a card disk having a central circular opening 2 centimetres in diameter, covered with tissue paper. In direct sunlight observe the bright surface of this circle of tissue paper (which serves as an artificial moon) through the mist that is produced in the globe by letting in a stream of moist vapour from a flask of hot water for a few seconds. The halo is yellowish with a red-brown edge.

[2] *Blue Sun.* Pour into the globe a little hydrochloric acid, and blow in air through the wash-bottle, having filled the latter first with liquid ammonia. A dust-cloud of fine particles of sal-ammoniac is thereby produced. A ray of direct sunlight viewed through this is curiously coloured, appearing at the first moment red, and then changing to bluish violet and to full blue.

[3] *Artificial Cloud-Glow.* For producing the intense diffraction colours of the cloud-glow it is necessary to procure a cloud consisting of small particles all about the same magnitude. This is best attained if the air before entering the globe is first led through hot water. If the conditions are favourable the colours are sufficiently intense as to permit of their being received on a white screen one metre distant. The colours change rapidly in a regular gradation of order, each colour appearing first at the centre of the field, and moving outwards.

Several additional phenomena are to be observed with this apparatus; and its inventor has devised an ingenious proof of the once-disputed point that the particles of mist are spherules, not vesicles. This he does by showing that certain diffraction phenomena which depend on the size of the particles remain unchanged during a sudden change of external pressure, which, if the particles were bubbles or vesicles, would at once cause them to expand.

ILLUMINATION OF MICROSCOPES AND BALANCES

IN measurements and weighings where high scientific accuracy is needed it is sometimes necessary to use artificial means of illumination, and it is found that when reflected light cannot be conveniently introduced, the heat from ordinary lamps causes variations of the temperature of the room, &c., which slightly affect the accuracy of the results to be obtained. By using, however, an incandescent electric lamp fitted inside a glass vessel of water, the light may be even brought near to the microscope or balance without any appreciable interference with temperature. The glass vessel is provided with a pierced cover or shade, and a little stream of water of a uniform temperature may be kept flowing through the vessel.

By means of a "chromozone" battery, supplied by Mr. O. March, it has been found, at the Standards Office, that a light may be maintained at an insignificant cost for fifty hours without, of course, any attention. During a recent comparison made by Mr. Chaney of two standard kilogram weights it became necessary to use the lamp, but the action of the balance was not interfered with by the proximity of the lamp, the probable error of the result being only ± 0·005 mgr.

NOTES

IN an overflowing Convocation at Oxford, on Tuesday, the battle of vivi-section was fought out a third time. The victory of sound sense over false sentiment has again been won; and on this occasion the vote is unmistakable. In spite of the most vigorous exertions of the opponents of physiology, the decree to endow the Physiological Laboratory—as the other scientific departments in the University are endowed—has been carried by the large majority of one hundred and sixty-eight. The Dean of Christchurch opened the debate in a moderate speech recommending the grant. He pointed out that the vote was for teaching purposes, and in no way concerned vivisection, for Prof. Burdon Sanderson had given the most complete assurances that he would not use painful experiments on living animals for the purposes of teaching. Canon Liddon opposed the decree on the ground that the Council should have introduced further safeguards against the indiscriminate use of vivisection. He admitted that vivisection was justified in certain cases, and spoke of it as a painful necessity. The Bishop of Oxford denied the moral right of man to inflict pain in order to advance knowledge, and declared vivisection to be degrading to the sensibility and humanity of the operator. The vote was supported by Prof. Dicey and Sir W. Anson, and unintentionally damaged by Dr. Acland. The last speakers were much interrupted by a clamour which prevented their remarks being heard. The announcement of the result—*placets*, 412; *non-placets*, 244—was received with great enthusiasm, both in the arena and in the undergraduates' gallery. It is to be hoped that this decisive vote will put an end to the warfare waged against the teaching of physiology in Oxford.

GEOLOGISTS throughout the world will be interested to learn that Dr. Franz Ritter von Hauer, who for so many years has so admirably guided the progress of the Geological Survey of Austria, has resigned his post as Director of that institution, and has been appointed Intendant of the Imperial-Royal Natural History Museum, Vienna. He carries with him into his new sphere of labour the hearty good wishes of a large circle of friends and well-wishers, who hope that the official duties he must now perform will in no way diminish the service he has rendered to science so long and so usefully.

IT has been proposed that, for the present session, in place of the formal receptions which have hitherto been held, the rooms of the Royal Society should be kept open on certain nights in order that Fellows and their friends may meet together for conversation and for the examination of such objects of interest as may be collected for the occasion. The first of these meetings will take place on Thursday, March 19, from 7.30 p.m. Any one desirous of showing on that evening any experiments, apparatus, or specimens illustrating any inquiry in which he may be engaged, should communicate with the Assistant Secretary, in order that appropriate arrangements may be made.

THE death is announced of the eminent Russian geologist George Helmersen, at the age of eighty-two. He studied at Dorpat under Engelhardt, whom he accompanied on his scientific journey along the course of the Lower Volga and the Ural. He subsequently took part in Hofmann's and Humboldt's explorations of the Ural region. Having completed his studies, especially in mineralogy, he spent some years, by direction of the Russian Government, in geological travels through Germany, Austria, and Switzerland. In 1835 he joined the body of mining engineers, and was appointed Director of Studies at the Mining Institute in St. Petersburg. During leisure periods he carried out a series of important geological journeys over the Kirghiz Steppe, through Norway and Sweden, the coal districts of Poland and Silesia, the mining districts of Lakes Onega and Peipus, and the bituminous coal region in the governments of Kherson and Kiev. He also thoroughly explored the gold mines at Beresovsk, and traced the course which has been followed in making the Ural Railway. The results of his indefatigable industry have been published in numerous memoirs of the Russian Academy of Sciences and other works.

WE have heard with regret of the untimely death of the eminent Russian naturalist, Mr. N. Severtsoff, which occurred on the evening of January 11, when driving across the Don, in the Government of Voronej, his horses and vehicle breaking through the ice. The coachman managed to extricate Mr. Severtsoff, but the thermometer stood at – 10° Reaumur, and, before he could be taken to a neighbouring village, he was frozen to death. It is a singular coincidence that Prof. Fedtchenko, another of the greatest of Central Asian naturalists, who, like Mr. Severtsoff, had so often risked his life in the pursuit of science in Turkestan, was also frozen to death in Europe. Mr. Severtsoff so early as 1867 explored the Thian Shan as far as the sources of the Naryn. His work on the vertical and horizontal distribution of Turkestan mammals was written in Russian, and he has since published original researches on the birds of the Pamir. Certain portions of his remarks on Turkestan mammals and birds have been translated, and it is chiefly to him that we are indebted for what information we have in English respecting the mammals, birds, and reptiles of

to see, however, from Messrs. Sampson ouncement of a book by Dr. Lansdell, , in which are promised the enumeration and flora, in about 20 lists, with intro-

ig tried in the Jefferson physical labora- *ience*, which promises to be successful. ock, with a wooden pendulum, is con- om the Harvard College Observatory, with no other mechanism than a fine spring connecting the pendulum to the armature of a telegraph instrument in the circuit. If the signals are interrupted during the day or night, the error of the clock, which seldom exceeds half a second in that time, will generally be rectified within an hour of their recurrence. The rate is in no way affected by the irregular signals caused in storms by the interference of the wires, and the regular impulses conveyed at intervals of two seconds increase but slightly the swing of the pendulum. The attachment can easily be made to any seconds clock at the cost of a few dollars, and may be of interest to those intolerant of the rates charged by companies for the use of electric dials.

FROM an article in the *Boston Journal* of February 7 we see that preparations are being made in the United States to observe the partial eclipse which will be visible there on March 16. Nearly 11/12ths of the sun's surface will be obscured at Washington, Baltimore, Philadelphia, New York, Boston, and Portland.

THE University of Glasgow having accepted the resignation of Dr. Bayley Balfour, the Chair of Botany in that University is now vacant. The patronage belongs to the Crown.

A PARLIAMENTARY paper published during the week (Corea, No. 1) contains, besides the trade report for Corea in the usual form, the account of a journey made by the Consul-General of Great Britain in the Peninsula. As for trade, the reports may be summed up much like the chapter on the snakes of Ireland: there is no trade, and there is no probability of there being any. The journey was from Seoul, the capital, to Songdo, to the north-east, the ancient capital of one of the three kingdoms into which Corea was divided. Some interesting information is given with regard to the production of the famous drug ginseng, so prized as a tonic by the Chinese. It is grown from a seed which is sown in March. The seedlings are planted out in beds raised a foot above the level of the surrounding soil, bordered with upright slates, and covered in from sun and rain by sheds of reeds, well closed in except towards the north side, where they are left to open. In the first or second year the ginseng plant is only two or three inches high, and has only two leaves. It is transplanted frequently during this period. In the fourth year the stem is about six inches high, with four horizontal leaves standing out from it at right angles, and in the fifth year a strong healthy plant has reached maturity, though it is more usual not to take it up until it has reached the sixth season. Ordinary ginseng is prepared by simply drying the root in the sun, or over a charcoal fire. To make red or clarified ginseng, the root is placed in wicker baskets, which are put in a large earthenware vessel with a closely-fitting cover, and pierced at the bottom with holes. It is then placed over boiling water and steamed for about four hours. Ginseng was for centuries regarded as a very elixir of life all over the East; and especially in China and Japan. Its properties were supposed to be miraculous, but they were generally supposed to be confined to the Corean ginseng. But its enormous price put it out of the reach of the poorer classes. The wild ginseng of Corea has frequently fetched twenty times its weight in silver in China. The export from Corea is a strict monopoly, which affords a considerable revenue, and is said to be the king's personal perquisite. Death is the punishment for smuggling it out of the country. The total export is only about 27,000 pounds avoirdupois.

ON February 8 died, near Hamburg, Johann Cæsar Godeffroy, until lately head of the great German firm of traders to the South Sea Islands. He was, however, much more than a merchant. Besides captains and supercargoes, he sent to Micronesia, Melanesia, Polynesia, and especially to Samoa, men of science, whose duty it was to make collections and send them to

Hamburg, to form there an exhaustive museum of natural history. The first whom he sent out on a mission of this kind was Dr. Graefe, of Zurich, now inspector of the zoological station at Trieste, who went to Samoa in 1861, and from this as a centre visited the Fiji, Tonga, and other groups in the region. He returned to Europe after eleven years, bringing with him important collections, and he undertook the editorship of a "Journal of the Godeffroy Museum." Amongst others thus despatched to the South Seas was a lady who spent ten years studying the botany of Northern Queensland, and a Polish surgeon, who lived for five years in the Marshall and Caroline Islands, then returned to Europe; returning again to the Carolines, where he is at present. A list of the men employed by Herr Godeffroy to travel in the South Seas to study the various islands, make collections for his museum, and report to him would embrace all nationalities, all departments of study, and every portion of the Southern Pacific. Eight catalogues of the Museum were published between 1864 and 1881, several of them containing zoological and geographical monographs as well. The *Journal*, which commenced in 1871, contained not only papers on the Museum and its contents, but was open to the discussion of any scientific subject connected with the South Sea Islands. Its most important feature was formed by the papers by specialists on sections of the collections sent home for the Museum. Fourteen parts were published in all, the most remarkable being on the fishes, which contained 140 plates and 312 illustrations. Through financial reverses this princely merchant died poor, and no purchaser was found for his museum, which will probably be broken up.

ACCORDING to a writer in the *North China Herald* on Chinese worship, it is certain that a great amount of fetichism prevails in that country. Near Peking, a few miles from the walls, on the east, is an enormous tree which fell more than two centuries ago, and which has been there ever since. It is called the Divine tree, and a temple has been erected for its worship. The people believe that a spirit lives in or near the tree, and should be worshipped from motives of prudence. The immense size of the tree is the result of the spirit's energy. It is believed it could not have grown so large without a present divinity. At Hantan, five or six days south from Peking, there are some iron bars in a well. In times of drought they are taken all the way to Peking to be prayed to for rain. They are placed in one temple after another, and prayers are offered to them till the showers fall. The bars are then reverently escorted back to Hantan, and placed in the well till they are again needed. In such a case the Chinese believe that there is a powerful spirit or genius in the well and in the bars, and that this spirit accompanies the bars to Peking and back again. This is Chinese contemporary fetichism, but in the ancient books there is no trace of fetichism. The objects of worship were either individual spirits or parts of nature. The ruling powers of the universe, from the highest to the lowest, were divided into four great classes—God, the subordinate heavenly powers, the higher earthly powers, and the numberless spirits that people earth and air. The subordinate heavenly powers were the seasons, the sun, moon, stars, cold and heat, floods and drought. The earthly powers were the gods of the mountains and rivers, and the last named are the spirits still remaining. Nothing is said of human spirits, though these were worshipped, then, as now, in the ancestral temples. But the worship in this instance consisted only of kneeling, prayer, and offerings.

DURING the late Health Exhibition at South Kensington the building and grounds were overrun with rats, food being plentiful and access to it comparatively easy. When the Exhibition closed, however, this ample source of provisions ceased to and starvation seized upon the hosts of rodents who had for six months increased and multiplied upon the fat of the land. For a long time they were to be observed scampering here and there for food with abnormal temerity, often fighting fiercely over fragments of refuse, which evidenced their extreme voracity; and the officials on duty in the building have reported that the rats abounded in such large numbers that the sound of their movements resembled the "sound of wind." By degrees, however, they disappeared, some dying of starvation, the majority emigrated to the houses in the neighbourhood, and at the present time there is scarcely one in the building.

IN connection with the Italian occupation of Massowah materials for a meteorological station are being sent to the place.

IN the report of the Berlin Physiological Society for Feb. 26 (NATURE, vol. xxxi. p. 404) the name of Dr. Kossel appears as Dr. Rossel.

IN the corrections in Sir William Thomson's Baltimore lecture given in last week's NATURE (p. 407), that for π should be π and π instead of ω and $\bar{\omega}$. Sir William Thomson also asks us to state that in his Bangor address (p. 410, 2nd line 12 from bottom) he has inadvertently given the date of coming to Glasgow as 1845 instead of 1846.

THE additions to the Zoological Society's Gardens during the past week include a Dwarf Common Ass (*Equus asinus*) from Tripoli, presented by Mr. J. Skelding; a Bonnet Monkey (*Macacus sinicus* ♂), a Macaque Monkey (*Macacus molgus* ♀) from India, presented by Mrs. M. Scott Carnegie; an Alexandrine Parrakeet (*Palæornis alexandri*) from India, presented by Mrs. Abbott; two Common Gulls (*Larus canus*), two Black-headed Gulls (*Larus ridibundus*) British, presented by Mr. F. S. Mosely, F.Z.S.; a Red Kangaroo (*Macropus erubescens* ♀) from South Australia. Coal Tits (*Parus ater*), British, purchased.

OUR ASTRONOMICAL COLUMN

VARIABLE STARS.—Prof. Schönfeld, in the notes to his catalogue of variable stars, which was published in 1875, refers to the singular circumstance that R Serpentis had not been observed at its minimum, though he doubted if it descended below the twelfth magnitude. Considering that the variability of the star was detected by Harding in 1826, the want of satisfactory determinations of the times of minima might hardly have been expected; it does not appear that our knowledge in this direction has advanced during the last ten years. Schönfeld's formula assigns for dates of maxima January 27, 1886, and January 19, 1886; the middle date is July 25, somewhere about which we may look for a minimum, though it is to be remembered that the increase of light has been observed to be more rapid than the decrease, especially near maximum. Observations made during the approaching summer, and continued as long as practicable, may perhaps lead to a well-determined result being put on record. The position of R Serpentis for the commencement of the present year is in right ascension 15h. 42m. 23·6s., declination +15° 29′ 3″.

A star in R.A. 14h. 8m. 0s., decl. −11° 15′·2 for 1855, is probably variable from at least 7·5m. to 10m. On April 10, 1854, it was estimated a tenth magnitude, at a subsequent date 8·5, and on March 18, 1874, it was as bright as 7·5. It is not in Lalande, Bessel, Santini, Lamont, nor in the Bonn Observations, vol. vi. It is entered on Harding's Atlas as a seventh magnitude.

THE OCCULTATION OF ALDEBARAN ON MARCH 21.—The disappearance of Aldebaran at its next occultation by the moon takes place while the star is yet above the horizon at Greenwich, but its altitude there will be less than 2½°. At Exeter the star disappears at 11h. 45m. 19s., Greenwich time, at an altitude of 4½°, so that there is a possibility of observations in the west of England.

THE NAVAL OBSERVATORY, WASHINGTON.—It is announced with an intention notified several months since, Commander

, Superintendent of the Observatory at Wash-
rogramme of work which it was proposed to
establishment during the present year. With
al, measures of a selected list of double stars,
tion or other peculiarity, are to be continued ;
f the inner satellites of Saturn will be observed,
micrometrical measurement of the rings are-
eas which have been commenced for stellar
nished. The Transit Circle is to be employed
the sun, moon, and larger planets, the latter
m fifteen to twenty times near opposition, and
minor planet will be observed at least five
le, near opposition. The 9·6-inch equatorial
r observations of all the minor planets whose
sition is greater than their mean brightness,
nets, and for occultations. The prime-vertical
is to be used in observing a selected list of
on with the Royal Observatory at Lisbon, in
n recommended by the International Geodetic
the determination of variability of latitude.
ircle observations will be made of stars down
agnitude, south of 10° north declination, the
h have not been recently determined at any
tory, the observatory list including stars in
eria Argentina not found in Yarnall's catalogue,
list of B.A.C. stars, or the recent catalogue
Observatory. These principal items in the
: that it is not intended that the Naval
fall short of its usual activity during the year

GEOGRAPHICAL NOTES

THE Australian journals which have arrived by the last mail contain full reports of the four days' conference of the Geographical Society of Australasia at Melbourne. Gen. Sir Edward Strickland was elected President, and Baron F. von Müller, Vice-President. The first resolution proposed that the term "Australasia" should be strictly defined. The expression was first used by Mr. Wallace, but it appears to have already had various inconsistent meanings applied to it. The proposer suggested that the following definition would serve all purposes : Australasia is that part of Oceania of which Australia is the geographical, commercial, and political centre. Limits : on the west and part of the north the 100° of longitude ; east, to the point of its intersection with the 20° south latitude, thence by a line running in approximate parallelism to the western and northern coast of New Guinea, and around its north-western extremity to the equator ; thence on the north, by the equator, to its intersection with the 120° of longitude west, and on the east by the 120° to the south pole, including groups of islands on the equatorial line. The question was ultimately referred to a strong committee. The next resolution affirmed the desirability of a scientific exploration of New Guinea under the auspices of the Society. A corollary calling on the Government to define the boundaries of the British possessions in that island was rejected in favour of one for complete annexation. The completion of standard works on the geography of Australasia, as well as of school maps, was also discussed. After much discussion it was decided that the consideration of the surest means for discovery of the fate of Leichhardt and his party should be left to the Colonial Councils of the Society, with a suggestion that a circular should be addressed to pastoral tenants in Western Queensland and Central Australia, requesting information on the subject. The formation of geographical societies, and their affiliation with the central body, in South Australia, Queensland, Western Australia, New Zealand, and Tasmania was also recommended. The next Conference will meet at Sydney.

AT the meeting of the Geographical Society of Paris on February 20 a communication was read from Dr. Gustave Le Bon, the author of a work on Arab civilisation, who is at present travelling in Nepaul. For the purpose of measuring the ancient monuments of various native states he has employed certain new instruments, which he will explain to the Society on his return a few months hence. Nepaul is closed to Europeans, and Dr. Le Bon is said to have been the first who has been permitted to travel through it.—M. de Lavigne spoke on the French law protecting cartographers from piracy, which he held to be unjust. A method of discovering counterfeits, adopted by certain French cartographers, is said to be the insertion of some street, town, or place with an imaginary name.—M. Pinart described a journey which he made in Chiriqui, in Panama, to study the manners, language, and monuments of the inhabitants.—M. Potel discussed the present situation of French trade in the River Plate.

FROM *Science* we learn that several expeditions to Alaska are projected during the coming season. Gen. Miles, commanding the military district of which the territory forms a part, desires to acquire a knowledge of the unexplored region between the head of Cook's Inlet and the Tananah watershed. The course of the Tananah is likewise unmapped, except from hearsay, though often traversed by traders in the last fifteen years ; so that the opportunity exists here for a fruitful expedition. It is hoped that arrangements may be practicable by which Lieut. Ray, well known for his successful direction of the Point-Barrow party, may be able to command such an exploration. The plan contemplates work either from the Yukon as a base, with a steam-launch and a small party, ascending in June and July, and returning before navigation closes, or an expedition by way of Cook's Inlet, making the portage to the Tananah, and then descending ; but a final decision is not yet reached. The party under Lieut. Abercrombie did not succeed in obtaining native assistance.

as expected, and were unable to pass beyond the glacier alleged to obstruct the Copper or Atna River, about sixty miles from the sea. Meanwhile, a party has actually started, under Gen. Miles's orders, January 30, for the Copper River, consisting of Sergeant Robinson and F. W. Ficket, signal-observer U.S.A., and commanded by Lieut. Allen. They intend to go in the mouth of the Atna or Copper River by steamer, and ascend as far as possible on the ice, pushing on by water as soon as the ice breaks up and the freshets are over. They hope to cross the divide from the Upper Atna, and descend by one of the Yukon tributaries to the mouth of the latter river, and rejoin civilisation at St. Michael's. They may be fortunate enough to make the journey in one season, but are prepared to stay two years. They will add a number of Indians to the party at Sitka, and carry various peace-offerings for the Atna Indians. Lieut. Stoney, of the navy, is reported to have a new expedition nearly organised to continue his investigations of the Kowak River. The plan adopted, so far as yet decided upon, is to take a steam-launch, ascend the river as far as possible, and pursue the explorations to its source, and winter in the region if necessary. It is stated that the party is to be composed of sixteen men, which is dangerously large, considering the limited food-resources of the region, and might be advantageously diminished by one-half for explorations in the interior. If the party were to pass over the divide, and investigate the course of the Colville, returning *viâ* Point Barrow next summer, it would accomplish a praiseworthy and much-needed investigation.

WE have received from Messrs. W. and A. K. Johnston a school physical wall map of England and Wales, in which the altitudes above sea-level are shown by varieties of tint. Of its kind this map is good, though we should prefer to see the method of tints combined with the graphic method, in order that pupils may be taught to read the maps with which they have to deal when they become men and women. Accompanying the map is a little hand-book of the physical geography of England and Wales.

THE SCOPE AND METHOD OF PETROGRAPHY[1]

IN considering the history of geology we are struck by the fact that towards the close of the last and during the commencement of the present century, when the science was taking rank as an important branch of human knowledge, petrography occupied a much higher position than it has at any subsequent period.

Werner, whose influence was almost unrivalled at the time to which I have referred, was a mineralogist, and his formations were therefore naturally based on the mineralogical characters of the different rocks. His observations were limited for the most part to his own district of Saxony, but he regarded his formations as sediments or precipitates from a universal ocean, and his numerous pupils, fired by his love of science and his intense enthusiasm, rejoiced in extending his classification to the districts with which they were severally acquainted.

The magnificent work of those who devoted special attention to the organic remains in the sedimentary deposits, and especially that of William Smith, the "Father of British Geology," had the effect of deposing petrography from the position which it held under the influence of Werner and his followers. It was clearly shown that the fossil contents of the strata were far more reliable as evidence of chronological relations than their lithological characters, and as soon as this became generally recognised, the reduction of the fossil-bearing rocks all over the world to something like definite order followed as a natural consequence.

The principle that strata may be identified by means of their fossil contents has not only proved applicable to the Secondary and Tertiary formations to which it was originally applied by Smith, Cuvier, and others, but it has been extended by Murchison, Sedgwick, Barrande, and others to the older rocks. Speaking broadly, there can be no doubt that over large areas the succession of the forms of marine life has been remarkably uniform from the Cambrian times down to the present, so that we have in the fossil contents of the different strata by far the most reliable means of determining chronological relations.

It is not surprising, then, that petrography has been comparatively neglected by geologists, for their main object during the present century has been to classify the stratified rocks which form so large a portion of the existing land surfaces.

At the present time, however, we are witnessing a great revival of interest in petrography, not only in this country but all over the globe. This is due in part, no doubt, to the introduction of new methods of research; but it seems to me that there are other and more general causes. The clear recognition of the great principle with which the name of William Smith is indissolubly united at once made it possible for a host of observers to do excellent work in every quarter of the globe. The interest awakened by the study of the geological structure of the most densely populated regions was akin to that which fills the geographical explorer of unknown lands. Until the main features of the geology of fossiliferous regions were described, it was not to be expected that observers would turn aside into a field of research in which they were certain to meet with snares for the purpose of attacking problems which, after all, are prove to be insoluble. As time went on, the unexplored areas in which fossiliferous rocks occur became more and more restricted, ne more and more inaccessible, and when the old chaos of Grauwacke fell into order before the brilliant researches of Sedgwick, Murchison, and Barrande, geologists were placed in an entirely new position. They had conquered that portion of the world which was open to their special method of attack. A number of fortresses still held out, it is true, and many of them remain unsubdued at the present day. They will doubtless occupy the attention of those who are most skilled in the old methods of warfare for many years to come. At the same time I think it will be admitted on all hands that the brilliant successes of the old generals have left a large portion of the army with little to do. We must, therefore, look for other worlds to conquer.

Now, on taking a general survey of the subject-matter of geology it will be seen at once that we are profoundly ignorant on questions relating to the origin and sequence of volcanic rocks, the cause or causes of volcanic action, the mode of formation of the crystalline schists, and the origin of mountains. To these questions are really unsolved is proved by the different of opinion which exists between competent observers. Another point which strikes one is, that if a solution of these problems be ever realised, it will be due in a great measure to the combination of field geology and petrography. This, it seems to me, will explain the great interest which is taken in the subbranch of science at the present day. If I am right in my opinion as to the present state of things, then we may safely predict that petrography will occupy as prominent a position the immediate future of geology as palæontology has done the past. In making this statement I trust it will not be supposed that I am claiming too high a position for that branch of geology with which I am most intimately acquainted.

Let us turn now to a more detailed consideration of the scope and method of petrography. The rocks of the earth's crust form the subject-matter of the science. Now these may be studied from two more or less distinct points of view—the descriptive and the æiological. We may set to work to describe the rocks, that is, to ascertain and record every possible fact with regard to them; or we may endeavour to trace the succession of events which has culminated in the state of things which we actually observe. It is perfectly obvious that we have no hope to attain any considerable success in the second branch of the subject until we have devoted a considerable amount of attention to the first.

Descriptive petrography then concerns itself with the chemical, mineralogical and physical characters of the individual rocks, and also with the distribution and mutual relations of the different varieties. The last-mentioned branch of the subject occupies the same position in petrography as comparative anatomy does in zoology. It may therefore be termed comparative petrography.

When the history of the science comes to be written, it will be recognised that it is to the Germans we are especially indebted for our knowledge of descriptive petrography. The amount of work which has been done in Germany is immeasurably greater than that produced by other nations. For years past they have been steadily improving their methods of observation, as well as observing and recording facts. Moreover, they have been training petrographers who are now scattered all over the world. Americans especially have availed themselves of the labours of Rosenbusch and Zirkel, and almost every Annual Report of the American Survey now bears witness to the rollers

[1] Lecture delivered in the Woodwardian Museum, Cambridge, by J. J. H. Teale, M.A., F.G.S.

a teaching point of view on the growth of petro-
ic. In this sketch, of course, I am only calling

yet another point of great importance to which atten-
ld be paid in subjecting a rock to an exhaustive
on. Owing to the brilliant researches of Sandberger,
ning to be recognised that many of the heavy and su-
e metals are present in ordinary rocks in minute
. Until recently we have been disposed to regard
tances as occurring only in mineral veins and in the
ortions of the earth from which the mineral veins have
posed to derive their supply of material. Now it is
to be clearly recognised that these substances are very
ributed even in the superficial crust of the globe. As
ation of the interest and practical importance of the
lowe referred to I may call attention to the important
Dr. Becker, on the "Geology of the Comstock Lode," published by the U.S. Geological Survey. This lode, of which is supposed to have sensibly affected the arkets of the world, occurs in a region which is re- for the extreme development of igneous rocks (diabase, ndesites, &c.), and for the widespread alteration to which cks have been subjected. The bisilicates, especially, n affected by this alteration, and for immense distances

Most careful assays have been executed, under the supervision of Dr. Becker, for the purpose of determining the amount of bullion in the fresh and unaltered rocks, and the relative amounts of gold and silver. He says: "By comparison of the different assays it appears that decomposed diabase carries somewhat less than half as much silver as the fresh rock. When the decomposed rocks are pyritous, the experiments made do not indicate any essential diminution of the gold contents. This fact, however, is quite possibly due to irregularity in distribution and the minuteness of the quantities of gold to be determined. As the decomposition of the rock in question has proceeded at a great depth beneath the surface, it is highly unlikely that silver should have been extracted unaccompanied by gold. Much of the decomposed rock, too, is nearly free from pyrite, and had the gold contents of such specimens been determined, a smaller percentage would probably have been found. The omission [to select specimens free from pyrite] was not detected until it was too late to resume the investigation. So far as quantitative relations are concerned, the silver only can be relied on, though the qualitative detection of gold as well is both interesting and important."

Another point of great interest was determined by Dr. Becker. He isolated the felspar and the augite of the diabase and tested both from silver. He found that for equal weights the augite was eight times as rich as the felspar substance, and as the latter contained some augite, this appears to furnish substantial proo that the silver is a constituent of the augite.

Having subjected a rock to exhaustive chemical and mineralogical examination, it next becomes necessary to compare it with other rocks, and to give it a name. The subject of nomenclature is a very difficult one. It is much to be regretted that notwithstanding all that has been done in descriptive and comparative petrography, we are still far from having any system of classification which is capable of general acceptance. Indeed, we are not agreed as to the first principles on which a classification of rocks should be based. The German petrographers, in most cases, adopt at the outset a principle which we cannot accept. They divide igneous rocks into older and younger: the former including all those which they regard as pre-Tertiary, the latter all those which are of post-Cretaceous age. The division is based, of course, on the assumption that the conditions of eruption in pre-Tertiary times were essentially different from those which have prevailed since. There seems, so far as we can judge, little or no ground for this assumption. The few facts which do at first sight lend support to it appear to be equally capable of explanation on the other hypothesis. The typical pre-Tertiary rocks of the German system are the granites, diorites, gabbros, diabases, and syenites. Now there is reason to believe that these are all plutonic rocks; in other words, that they are the result of slow consolidation beneath the surface, and therefore under great pressure. If this view be correct then their exposure at the surface can only occur long after their formation, and the fact that the majority of those known to us should be of pre-Tertiary age, as Lyell long ago pointed out, need occasion no surprise.

Again, it must be remembered that the mere association of eruptive rocks with pre-Tertiary deposits is no proof in itself that the former are of pre-Tertiary age, and also that many competent observers believe that these are clear cases of Tertiary granite, diorite, diabase, and gabbro.

The igneous rocks, which are regarded by the German petrographers as especially characteristic of the post-Cretaceous period, are the basalts, andesites, trachytes, and rhyolites; in other words, the surface-products of volcanic action. That these should be mainly Tertiary, and that they should differ to a certain extent from their pre-Tertiary equivalents in consequence of alteration, is only what might be naturally expected. This, however, is not sufficient to justify the refusal to give the same name to different specimens of one and the same rock merely because they have been produced at different periods; and the work of Allport, Bonney, Geikie, and others has proved that there are basalts, andesites, and rhyolites of Palæozoic age which are identical in structure, composition, and mode of occurrence with modern rocks.

In the absence of any generally recognised system of nomenclature it becomes difficult to assign a name to the rock of the Whin Sill. It is a holo-crystalline rock composed essentially of plagioclase, pyroxene, titaniferous and magnetic iron ore. In sections the felspar occurs in lath-shaped forms. To such a rock, provided it be of pre-Tertiary age, Rosenbusch would

give the name *diabase*. We are inclined, on the other hand, to call the rock a dolerite. The important point for the student to remember, however, is that in the present unsettled state of nomenclature his primary duty is to make himself familiar with the structure and composition of the various rock types. The question of names is, after all, only of secondary importance, provided we remember that in looking at the facts through the medium of an unphilosophical nomenclature we may so distort them as to fail to realise their true forms and relations.

Consider now the æiological aspect of petrography. Most of us are so constituted that we cannot rest satisfied with a mere description of facts; we almost instinctively endeavour to discover what we call the origin of things. This, after all, merely consists in tracing back as far as possible the chain of events of which the object or phenomenon in question represents the last link. The search after causal relations in the organic world has led to the introduction of a principle which is now recognised as one of the greatest importance in almost every branch of human knowledge. Changes in the characters of organisms are now admitted to be determined by two factors—the inherent properties of the organism and the influence of surrounding circumstances. A very little consideration will serve to shew that the changes which occur during and subsequent to the development of minerals and rocks are determined by two allied factors.

Take the case of crystallogenesis. It is not difficult to see in a general kind of way that the characters which a crystal possesses have been determined (1) by the inherent properties of the crystallising substance, and (2) by the influence of surrounding circumstances—of the environment. When we examine thin sections of rocks, furnace-slags, or the refuse products of glass-works, we frequently find a number of bodies which are intermediate as it were between glass and true crystals. These have been carefully examined and admirably described by Hermann Vogelsang, who has also succeeded in producing many of them by artificial means. As they serve to illustrate in a very striking way the principle above referred to, a short description of Vogelsang's experiments will not be out of place.

The crystallising substance finally selected by Vogelsang for the purpose of his experiments was sulphur. This substance is readily soluble in bisulphide of carbon, out of which it crystallises in the rhombic form. If the process of crystallisation be followed under the microscope, nothing definite as to the nature of crystalline growth can be made out. The first objects which appear are definite crystals, and these grow by accretion. If, however, the solution of sulphur be thickened with Canada balsam then, provided the proper proportions of the different substances have been employed, some very interesting phenomena may be observed by the aid of the microscope as the bisulphide of carbon evaporates. Minute fluid spheres arise in the medium and grow by mutual absorption. They finally consolidate as clear, transparent, isotropic bodies, and to them Vogelsang has applied the term globulites. It is impossible to determine absolutely the composition of these globulites, but there seems no reason to doubt the conclusion of Vogelsang that they are portions of the Canada balsam which are richer in sulphur than the surrounding mass, and that they arise in consequence of the attempt of sulphur to crystallise under unfavourable circumstances. Similar bodies may be observed in certain rocks, slags, and blow-pipe beads, although the crystallising compounds must be very different in the different cases.

Under certain circumstances the mass of sulphur and Canada balsam solidifies with the formation of globulites, but under other circumstances additional phenomena may be observed. When the resistance of the medium is too great to prevent the union of the globulites, but not too great to prevent their approach, they become united into various more or less definite forms. The mode of union depends partly on the way in which the globulites attract each other, and partly on the movements in the mass. A linear arrangement of the globulites is very common, and to the form arising in this way Vogelsang has given the name margarite. A rectangular grouping is also not uncommon. From a study of the various forms arising in consequence of the union of globulites, Vogelsang concludes that in the case of sulphur there are in each globulite, as it were, three directions at right angles to each other, in which the attraction is considerable, and that in one of these the attraction is decidedly greater than in the other two.

The building up of the compound forms naturally leaves the surrounding space free from globulites.

Under certain circumstances the globulites become flattened, if were, at the points of contact. This occurs when the resistance is sufficient to prevent the assumption of the spherical form, but not sufficient to resist the destruction of the pellicle at the point of contact. In this way rod-like bodies, termed longulites, arise.

It must be remembered that all these forms are strictly isotropic. They are not, therefore, in any sense of the word crystals. The moment a true crystal of sulphur appears, it can be recognised by its doubly-refracting properties. They have been termed crystallites, wherever they occur, by Vogelsang, and they evidently arise in consequence of the attempts of some definite chemical compound to crystallise under conditions which do not admit of the free approach of the molecules.

Between crystallites and perfect crystals showing definite external faces there are numerous intermediate forms, such as microlites and skeleton crystals. As further illustrations of the influence of the environment we have only to consider the fact that no two crystals of the same substance are precisely alike in all their characters, and that some substances, like sulphur and carbonate of lime, may be made to crystallise in two different systems by varying the conditions under which the crystallisation is effected.

There can be no doubt, then, that two factors are involved in the determination of the properties which crystals possess—the inherent forces of the crystallising substance and the influence of surrounding substances.

So far we have referred only to the birth and growth of crystals. But the history of a crystal does not cease with its formation. With a change in the surrounding circumstances the crystal may be modified or destroyed. Thus we now find crystals have a kind of life-history; they are born, they grow in size by accretion, and finally they cease to exist as distinct individuals.

As an illustration of the influence of a change of physical condition on the character of a crystal, consider the case of leucite. At ordinary temperatures this mineral is generally regarded as tetragonal, and it certainly shows double refraction in thin sections. Klein has shown that by heating leucite to a point far short of its fusibility it may be rendered perfectly isotropic, and hence follows the conclusion that leucite is really isotropic when subject to the conditions under which it is formed. That crystals should be in a state of stable equilibrium, so far as molecular forces are concerned, when subject to the physical conditions under which they are formed, is exactly what we should expect, and that this equilibrium may be disturbed by a change in these conditions is also very easy to understand.

As further illustrations of the principle here referred to, consider the various cases of paramorphosis, such as the change from aragonite to calcite, or from calcite to aragonite; or, again, the corresponding changes in sulphur.

Illustrations of the changes which arise in crystals in consequence of changes in the chemical conditions to which they are subjected, need not here be referred to in detail; the occurrence of crystalline rocks by denudation is of course a consequence of these changes.

Consider, now, the rocks of which the earth's crust is composed. They also have a life-history. They are formed and destroyed, and it is the business of the petrographer not only to describe and classify them, but also to trace out the cycle of change. For the purpose of illustrating this branch of petrography let us consider certain facts with reference to the genesis of crystalline igneous rocks. It will be admitted that all those that such rocks as granite, syenite, diabase, rhyolite, trachyte, andesite, and basalt have originated by the consolidation of an intensely heated silicate-magma under different conditions of temperature and pressure. The consolidation has been accompanied—except in those cases where the magma has been solidified as a homogeneous glass, and these will be left out of account for the present—by the development of crystals. To these, then, we would understand the manner in which crystals of crystallogenesis in silicate-magmas. Numberless facts need not here be referred to prove that the process of consolidation is not a sudden one. As the surrounding circumstances (environment) become more and more favourable to consolidation, the minerals separate out one after the other, until at last the whole mass becomes solid, and the rock is formed. The temperature at which any given mineral forms is not determined by its own fusibility. The laws of the formation of mineral

e arrived. Now I think we
kind in the present case. It

will be admitted on all hands that the crystals in porphyritic rocks, such as hypersthene-andesite, have been formed in a magma the composition of which is represented by the bulk analysis of the rock. If, then, we compare the bulk analysis with the analysis of the ground-mass deprived of its crystals, we ought to find confirmation of the above conclusion.

Dr. Petersen has isolated and analysed the ground-masses of two of the Cheviot porphyritic rocks, and by comparing these with the bulk analyses of the rock the truth of the conclusion is most strikingly illustrated. The effect of progressive crystallisation in the andesitic magma has led unquestionably to an increase in the amount of silica, a decrease in the amounts of lime, iron, and magnesia, an increase in the amount of alkalies generally, and an increase in the potash relatively to the soda. In the rock itself soda is in excess of potash; in the ground-mass potash is in excess of soda.

There is yet another piece of independent confirmatory evidence. Every geologist is familiar with the phenomenon of contemporaneous veins. The general view held with regard to them is that they represent portions of material which remained fluid after consolidation had progressed to a considerable extent. If this view be correct, then they should hold the same chemical relation to the main mass of the rock as the ground-mass of the Cheviot andesite does to the main mass of the andesite. Mr. Waller has recently analysed certain contemporaneous veins which occur in the bronzite-diabase of Penmenmawr. He finds that they contain about 7 per cent. more silica than the normal rock, less lime and magnesia, more alkalies, and more potash than soda, although in the normal rock soda is in excess. Contemporaneous veins in the Rowley rag dolerite have also been investigated by Mr. Waller, with the same result as far as increase in silica and total alkalies is concerned. The relation of potash to soda has not yet been determined.

I believe it is admitted to be a general rule that contemporaneous veins contain more silica than the rock with which they are associated. It will be seen that there is abundant evidence of an independent character to confirm the general truth of the conclusion which follows from a consideration of the facts brought forward by Rosenbusch.

I should not have treated this subject at such length did it not appear to have an important bearing on the origin and sequence of volcanic rocks. I can best explain this by referring to the Cheviot district, with which I am slightly acquainted.

Andesitic lavas and tuffs cover large tracts of this district. These are unquestionably the products of surface volcanic action. In the central portion of the volcanic area there is a mass of augitic granite. A consideration of the mineralogical composition of this granite shows that it cannot belong to the acid group of rocks, and this conclusion is confirmed by an examination of the chemical composition of allied rocks from the Vosges. So far as we can judge in the absence of analyses there appears to be a very close connection between the composition of the plutonic and that of the volcanic rocks of the Cheviot district, and we therefore seem justified in concluding that the plutonic masses differ in character from the andesitic lavas merely in consequence of differences in the conditions of consolidation. The plutonic rocks represent the consolidation of the andesitic magma beneath the surface, and therefore under great pressure; the lavas and tuffs represent the consolidation of the same magma at the surface.

I now come to the point to which I wish to direct special attention. The andesitic lavas and tuffs are traversed by quartz-felsite dykes in such a way as to show that a magma of rhyolitic composition must have been erupted by the Cheviot volcanoes subsequently to the period characterised by the eruption of the andesitic magma. Contemporaneous veins, similar in character to the quartz-felsite dykes also occur in the plutonic rocks. Again, an analysis of one of the quartz-felsite dykes by Mr. Waller agrees almost exactly with the analyses of the ground-mass of the hypersthene-andesite by Dr. Petersen.

Putting all these facts together, we conclude that the eruption of an andesitic magma was followed, in the history of the Cheviot volcanoes, by that of a rhyolitic magma in consequence of progressive crystallisation in the deep-seated plutonic source. The rhyolitic magma is, so to speak, the mother liquor out of which various basic minerals have crystallised. Suppose a half-consolidated plutonic mass, originally of andesitic composition, to become subjected to a powerful crush such as that which unquestionably arises in the earth's crust under certain circumstances. The mother liquor will be squeezed out of the mass,

like whey out of cheese, and it may finally consolidate as contemporaneous veins in the plutonic rock, as dykes in the surrounding volcanic rocks, or as rhyolitic lavas and tuffs at the surface. The ideas here thrown out appear to me to be capable of extension to other volcanic regions; but as the sequence in these regions is generally complicated by the coming in of basic rocks during the later phases of volcanic activity, it will not be advisable to enter more fully into the subject on the present occasion.

The special characters which igneous rocks present, then, are to be traced to the chemical and physical properties of the original magmas and to the influence of surrounding circumstances. Rocks, like minerals, are in a state of stable equilibrium when subjected to the conditions of their formation. When subjected to other conditions, whether physical or chemical, they usually undergo a change. The destruction and disintegration of igneous rocks by the various agents of denudation are familiar to every student of geology, and need not therefore be described on the present occasion.

I trust I have now said sufficient to show that the science of petrography is one of the greatest importance to the geologist of the present day. The remarks on ætiological petrography are, of course, only intended to illustrate the nature of this branch of the subject, and to show that conclusions of the greatest theoretical interest may be expected to follow from a careful consideration of the facts acquired by work in the other branch of the science.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—A Report recently issued gives particulars of the successful raising of the roof of the Mineralogical Museum to form a Morphological Laboratory on the new floor thus created. The firm of builders who had furnished estimates ultimately declined the work, and the Department of Mechanism undertook it. Under the continual superintendence of Prof. Stuart and Mr. Lyon the work was so skilfully done that not a crack was occasioned in the ceiling of the Mineralogical Museum, and the deflection of the new timbers was so well calculated that no timber moved upwards or downwards more than the eighth of an inch when the load came upon it. The cost was several hundred pounds less than the estimate. The roof raised was 110 feet long, and the weight fifty tons. A special vote of thanks is to be given to the Department of Mechanism for the care, skill, and economy with which the building operations were conducted.

The Botanical Laboratory has cost a little over 800*l.*; the Morphological Laboratory has cost about 2500*l.*

In the Natural Science "Special" Examinations for the ordinary B.A. degree during the past year, the great majority of candidates chose Chemistry, and showed that they had bestowed considerable pains on laboratory work while yet they were only imperfectly acquainted with the *rationale* of the processes they employed. The candidates in Botany had neglected systematic, and especially descriptive, botany. In June the descriptions of easy, well-marked specimens of flowering-plants were so worthless, that it was difficult to find out, from some descriptions, to which of the specimens they were intended to apply.

In Mechanism and Applied Science book-work was satisfactorily done, but deductions and numerical applications were very imperfect. Drawing was well done, and the candidates also showed a practical acquaintance with the use of tools; but they did not sufficiently connect their mathematical with their practical knowledge.

In the previous examination or little-go, Jevons's logic was set as an alternative subject to Paley with considerable success last year. Out of forty-four candidates only six failed. In arithmetic a knowledge of decimals and the use of common sense were strikingly wanting. The gradual elevation of standard in Euclid and Algebra of late years appears to have produced beneficial results. The papers in Mechanics in the October examination (on entrance) were unsatisfactorily answered; the candidates had for the most part read treatises dealing with the subject incompletely and popularly.

The proposal to discontinue entirely the additional examination in Mathematics for Honours Candidates has been rejected by a large majority, it having been found impossible to provide any substitute which would command general assent.

Mr. M. C. Potter, Assistant Curator of the Herbarium, has been approved as a Teacher of Botany.

The Physiological class-rooms having again become serious overcrowded, owing to the increase of the medical school, a scheme for building new class-rooms with a large lecture-room put forward by the Museums and Lecture Rooms Syndicate. The lecture-room is to be 45 feet by 40, and 32 feet high, and is calculated to accommodate 247 students comfortably. A new class-room 80 feet long to accommodate 100 students working at one time is an important feature, and rooms will also be provided for Prof. Roy's temporary Pathological Laboratory. The estimate cost is 9000*l.*

SCIENTIFIC SERIALS

Journal of Anatomy and Physiology, January, contains:—Diseases of the reproductive organs in frogs, birds, and mammals, by J. B. Sutton (plate 8).—Oviduct in an adult male skate, by J. D. Matthews (plate 9).—On the influences of some conditions on the metamorphosis of the blow-fly, by J. Davidson.—On sources and the excretion of carbonic acid at the liver, by J. Charles.—On a method of maceration, by A. M. Paterson (plate 10).—Floating kidney, by D. Hepburn.—The movements of the ulna in rotation of the fore-arm, by Thos. Dwight.—On section of a double monster, by A. Hill.—Relation of the alveolar form of cleft palate to the incisor teeth and the intermaxillary bones.—The dumb-bell-shaped bone in the palates of Ornithorhynchus compared with the pre-nasal bone of the pig.—The infra-orbital suture; and an additional note on the cranium of the Greenland shark, by W. Turner.—Anatomical notes.

Quarterly Journal of Microscopical Science, January, contains:—On the significance of Kupffer's vesicle, with remarks on other questions of vertebrate morphology (plate 1), by J. T. Cunningham.—Blastopore, mesoderm, and metameric segmentation, by W. H. Caldwell (plate 2).—On the origin of the hypoblast in pelagic teleostean ova, by G. Brook.—On the presence of eyes in the shells of certain Chitonidæ, and on the structure of these organs, by H. N. Moseley (plates 4, 5, 6).—*Archerina boloni*, nov. gen. et sp., chlorophyllogenous proto soon allied to Vampyrella, by E. Ray Lankester (plate 7).—On the apex of the root in Osmunda and Todea, by F. O. Bower (plates 7 and 8).—Correction of an error as to the morphology of *Welwitschia mirabilis*, by F. O. Bower.—E. Van Beneden's researches on the maturation and fecundation of the ovum, by J. T. Cunningham (plate 10).—On the suprarenal bodies of vertebrata, by W. F. R. Weldon (plates 11 and 12).—On the life-history of certain British heteropleural annelines, by C. Plowright.—On the occurrence of chitin as a constituent of the cartilages of Limulus and Sepia, by W. D. Halliburton.

Journal of the Royal Microscopical Society, February, contains:—On the apparatus for differentiating the sexes in bees and wasps. An anatomical investigation into the structure of the receptaculum seminis and adjacent parts, by F. R. Chadwick (plates 1 and 2).—On the occurrence of variations in the development of a Saccharomyces, by G. F. Dowdeswell.—Notes on the life-histories of some little-known Tyroglyphidæ, by A. D. Michael (plate 3).—The usual summary of current researches in zoology, botany, and microscopy.

THE *American Naturalist*, February, contains:—On the habits of some Arvicolinæ, by E. R. Quick and A. W. Butler.—On a parasitic copepod of the clam, by R. R. Wright.—On the rudimentary hind-limb of Megaptera, and on the fingermuscles in *M. longimana* and in other whales, by J. Struthers.—The structure and development of the suspensory ligament of the fetlock in the horse, by J. D. Cunningham.—The Wisconsin or Wakefield marble of Vermont, by G. H. Perkins.—A botanical study of the mite-gall found in the black walnut, by Lucy J. Martin.—On the evolution of the Vertebrata, progressive and retrogressive, by E. D. Cope.

Rendiconti del Reale Istituto Lombardo, January 8.—A report on the work of the Institute in the various branches of science and letters during the past year, by the Secretary.—Biographical notice of Baldassare Poli, by Prof. Carlo Cantoni.—January 15.—On the secular variations in the elements of terrestrial magnetism at Venice, by Ciro Chistoni.—On a rare case of congenital malformation of the bladder, by Dr. G. Fornaca.—On the Extent of the diurnal oscillation of the magnet of declination at Milan in the year 1884, by Prof. G. V. Schiaparelli.—On the anatomy of the human brain, by Dr. Cesare Mirabelli.

earance of Halley's comet in the year 1456, by Prof. G.

ta Scientifico-Industriale, January 15.—Influence of static ty on lightning conductors, by Prof. Eugenio Canestrini. rouvé's universal incandescent electric lamps (four illus-), by the Editor.—On the various forms of *Scleranthus tus*, Gussone, by Dr. Leopoldo Nicotra.

chrift für wissenschaftliche Zoologie, December 1884, 2.—Observations on the origin of the sexual cells in by Dr. C. Hartlaub (plates 11 and 12).—Studies among oebue, by Dr. A. Gruber (plates 13 and 14).—On the tion and development of *Ratifer vulgaris*, by Dr. O. as (plate 16).—On the amœboid movements of the tozoa of *Polyphemus pediculus*, by Dr. O. Zacharius.— mropneustic system in Helicinæ, by Dr. H. v. Ihering 7).—On the metamorphosis in Nephelis, by Dr. R. S. (plates 18 and 19).—On the intercellular spaces and in epithelia, by P. Mitrophanow.

hologisches Jahrbuch, Band 2, Heft 3, contains :—On the ice of spindle-shaped bodies in the yolk of young frog y Prof. O. Hertwig (plate 14).—Researches upon the *dominales*, by H. Ayers (plate 15).—Contribution to a lge of the eye in gastropods, by C. Hilger (plates 16 and l a postscript by Dr. O. Bütschli.—Studies on the deve- of the medullary cord in bony fish, with observations on appendages of the germinal vesicle and the chorda dor- Salmonidæ, by N. Goronowitsch (plates 18 to 21).— irs and birds ; a reply to Prof. W. Dames, by Dr. G. On the carpi centrale, and on the morphology of the n the Mammalia, by Dr. G. Baur.—Remarks on the al pores in fish, by Prof. C. Gegenbaur.

SOCIETIES AND ACADEMIES

LONDON

l Society, January 15.—"On the Constant of Electro- c Rotation of Light in Bisulphide of Carbon." By Lord , F.R.S.

aplete account is here given of the experiments briefly to in the Preliminary Note,[1] and of others on the same more recent date. As regards the method, it may be to add to what was there said, that the electric currents imated by comparing the difference of potential gene- the current in traversing a known resistance with that ndard Clark cell, the value of the cell being known by operations, in which the current was measured by a lectro-magnetic apparatus.[2] Allowance being made for ture, the determination of the currents by this method ndustly accurate and very simple.

esults are grouped in three series, of which the first two sidered in the Preliminary Note. In both of them the e was used, the principal difference being that in the light traversed the tube three times, and in the second . In the third series another tube was employed, and provements in respect to thermal insulation were intro- The readings were taken with a double-image prism in the ordinary analysing Nicol, a substitution by which it ed some advantages were obtained.

the fifteen sets of observations of Series I. we find as ion of sodium light in bisulphide of carbon at 18° corre- to a difference of potential equal to unity C.G.S. the 1203 minute. From the four observations of Series II. in like manner ·04198 minute, and from the seven ions of Series III. ·04202 minute. The last value is as the most probable.

appendix some remarks are made upon polarimetry in especially in relation to the half-shade method. A roposed by M. Becquerel for augmenting the precision ch rotations can be determined with the aid of a half- te is considered, and the conclusion is arrived at that tage can thus be obtained.

ary 19.—"Note on a Preliminary Comparison between s of Cyclonic Storms in Great Britain and those of Disturbances at the Kew Observatory." By Balfour F.R.S., and Wm. Lant Carpenter.

thors had made this comparison, through the kindness

[1] *Roy. Soc.* vol. xxxvii. p. 146.

[2] "On the Electro-chemical Equivalent of Silver, and on the Absolute ue Force of Clark Cells." *Proc. Roy. Soc.*, vol. xxxvii. p. 142.

of Mr. Whipple, in the case of about thirty storms, the dates of which were taken haphazard from those given by Mr. R. H. Scott in his paper on the cyclonic storms of the last ten years, in the *Quarterly Journal* of the Meteorological Society for October, 1884. Out of these thirty cases, in twenty-three there was a distinct magnetic disturbance, for the most part preceding the storm by somewhat more than a day. The authors intend to pursue the subject, considering that there is a *primâ facie* case for investigation.

Geological Society, February 20.—Annual General Meeting.—Prof. T. G. Bonney, F.R.S., President, in the chair.—The Council's Report announced the awards of the various medals and of the proceeds of the Donation Funds in the gift of the Society.—In handing the Wollaston Gold Medal to Dr. W. T. Blanford, F.R.S., for transmission to Mr. George Busk, F.R.S., F.G.S., the President addressed him as follows :—The Council of the Geological Society has awarded to Mr. George Busk the Wollaston Medal in recognition of the value of his researches in more than one branch of palæontology. Polyzoa, not only fossil, but also recent, he has made peculiarly his own, and his numerous separate papers, his British Museum Catalogue, and his memoir on the Polyzoa of the Crag, have entitled him to the lasting gratitude of workers at this class of the Mollusconda. But, perhaps as a relief to the study of these minute invertebrates, he has occupied himself, not less successfully, with the larger vertebrata, so that to him we are indebted for much information on the fauna of Post-tertiary deposits, especially from the caves of Malta and of Brixham. Permit me, in handing you this medal for transmission to Mr. Busk, to express my pleasure at having such a duty to discharge, and my earnest hope, in which I am sure all present will share, that restored health may enable him to continue his work in the cause of our science.—The President then presented the balance of the proceeds of the Wollaston Donation Fund to Dr. Charles Callaway, F.G.S., and addressed him as follows :—The Council of the Geological Society has awarded to you the balance of the proceeds of the Wollaston Donation Fund, in recognition of the value of your researches among the older British rocks. By your identification of Upper Cambrian rocks in Shropshire you have placed beyond question the antiquity of the Rhyolitic Group of the Wrekin, our knowledge of which and of yet older rocks in that district you have greatly augmented. Your contributions also to the geology of Anglesey and to unravelling the stratigraphy of the Scotch Highlands have been of great value, and we look forward to the results of further researches, in aid of which I have great pleasure in placing in your hands the amount of the award. That you receive it from a fellow-labourer will, I hope, make it not the less welcome. The President then handed the Murchison Medal to Dr. Henry Woodward, F.R.S., for transmission to Dr. Ferdinand Römer, F.M.G.S., of Breslau, and addressed him as follows :—The Council has awarded to Dr. Ferdinand Römer the Murchison Medal and a sum of ten guineas from the Donation Fund. His life-long and unwearied labours in the service of our science have long since made his name familiar to his fellow-workers. When I state that the Royal Society Catalogue, published now more than eleven years since, records the titles of 122 separate memoirs written by him, when I mention his other important works, such as that on "The Chalk Formation of Texas," on "The Silurian Fauna of Tennessee," on "The Geology of Upper Silesia," and the "Lethæa Geognostica," I have said enough to prove that this memorial of an illustrious geologist could not well have been bestowed on a more illustrious recipient. In transmitting it to Dr. Römer, he so find as to express our regret that the distance and the season of the year have deprived us of the pleasure of his presence on this occasion. In presenting the balance of the proceeds of the Murchison Geological Fund to Mr. Horace B. Woodward, F.G.S., the President addressed him as follows :—The balance of the proceeds of the Murchison Donation Fund has been awarded to you in recognition of the good service which you have already rendered to geology, especially by your work among the later deposits of the eastern counties, and to aid you in further researches. For the excellent papers which you have written, in addition to the work done by you as a member of the Geological Survey, do not constitute your only claim to our recognition. You have made use of the opportunity of your official position to promote a love of science among those who live in our eastern counties, and we are indebted to you for that admirable volume, "The Geology of England and Wales," which, though in one sense a compilation, is such a one as only

a skilled geologist could produce. The President next presented the Lyell Medal to Prof. H. G. Seeley, F.R.S., F.G.S., and addressed him as follows:—The Council has awarded to you the Lyell Medal and a grant of 40*l.* in recognition of your investigations into the anatomy and classification of the Fossil Reptilia, especially the Dinosauria. Not that you have limited yourself to this field of research; your papers on *Ewyas* and *Pterhaphorus*, on *Megalornis* and British Fossil Cretaceous Birds, on *Zeuglodon*, and on remains of Mammalia from Stonesfield, prove your extensive knowledge of vertebrate palæontology, as your proficiency in invertebrate is evidenced by your earlier work, both stratigraphical and directly palæontological. Furthermore, your excellent edition of the first volume of Phillips's "Manual of Geology" indicates an exceptional familiarity with the literature of our science. Since our acquaintance first began, some twenty years since, at Cambridge, we have both had our disappointments and our successes; you, undiscouraged by the one, unelated by the other, have pushed on to your present high position in science, making no enemies, winning many friends. I trust that your future career may be even more prosperous than your past, and that this medal may be an augury of many good gifts of fortune. You will, I know, believe me when I say that I feel an exceptional pleasure in being commissioned to place in your hands this medal, commemorative of the great geologist whose philosophic spirit you so well appreciate, and whose memory, I know, you so greatly revere. The President then handed the balance of the proceeds of the Lyell Geological Fund to Mr. J. J. H. Teall, F.G.S., for transmission to Mr. A. J. Jukes-Browne, F.G.S., and addressed him as follows:—The balance of the Lyell Donation Fund has been awarded to Mr. A. J. Jukes-Browne in recognition of the excellent work that he has done on the Cretaceous formation and on glacial geology, and to aid him in further researches. His papers on the Cambridge greensand cleared up many difficulties connected with that interesting formation; and in his Sedgwick prize essay on the Post-tertiary deposits of Cambridgeshire he commenced those investigations which have since brought us more than one valuable contribution on glacial and later deposits. You can tell him that his old college tutor feels a little pardonable pride and much real pleasure in being the instrument of placing this award in your hands for transmission to him. In presenting the Bigsby Gold Medal to Prof. Renard, of Brussels, the President addressed him as follows:—When to a familiarity with geology in the field and a love of nature are united the skill of a finished chemist and the experience of a practised worker with the microscope, the results cannot fail to be of the utmost importance to our science. These qualifications, rarely united in any one man, are in yourself combined with an untiring industry and a love of science for its own sake. Thus we are indebted to you for many important contributions to our knowledge in geology. Your early memoir, "Sur les Roches Plutoniennes de la Belgique et de l'Ardenne Française," written in conjunction with M. de la Vallée Poussin, will long be classic; your papers on various subjects connected with the Carboniferous limestone, on the coticule, the phyllites, and other altered rocks of Belgium, and on the deep-sea deposits, are too well known to need more than mention, and in recognition of these the Council has awarded you the Bigsby Medal. In placing it in your hands may I be allowed to express for myself and others the hope that it will be always a pleasant *souvenir* of your many friends on this side of the Channel, some of whom, myself included, will not soon forget the pleasant and, to us, most profitable days spent under your guidance in geological studies by the limestone cliffs of the winding Meuse and the wooded crags of the Ardennes. The President then read his Anniversary Address, in which, after giving obituary notices of some of the members lost by the Society during the year 1884, he referred to the principal contributions to geological knowledge which have been made during the past year, both in the publications of the Society and elsewhere in Britain, concluding with a notice of the new views which have been adopted with regard to the structure of the Western Highlands, and a brief history of the steps by which they have been arrived at. The concluding portion of the address was devoted to a discussion of the principles of nomenclature which should be followed in petrology, with remarks on the classification of igneous rocks, and on the significance of certain structures, especially the more minute.—Officers and Council, 1885:—President: Prof. T. G. Bonney, F.R.S.; Vice-Presidents: W. Carruthers, F.R.S., John Evans, F.R.S., J. W. Hulke, F.R.S., J. A. Phillips, F.R.S.; Secretaries: W. T. Blanford, F.R.S., Prof. J. W. Judd, F.R.S.; Foreign Secretary: Warington W. Smyth, F.R.S.; Treasurer: Prof. Wiltshire, F.L.S.; Council: H. Bauerman, W. T. Blanford, F.R.S., Prof. T. G. Bonney, F.R.S., W. Carruthers, F.R.S., Prof. W. Boyd Dawkins, F.R.S., John Evans, F.R.S., Sir A. Geikie, F.R.S., Henry Hicks, M.D., Rev. Edwin Hill, M.A., G. J. Hinde, Ph.D., John Hopkinson, W. H. Hudleston, F.R.S., J. W. Hulke, F.R.S., Prof. T. Rupert, F.R.S., Prof. J. W. Judd, F.R.S., J. E. Marr, M.A., J. A. Phillips, F.R.S., Prof. J. Prestwich, F.R.S., Warington W. Smyth, F.R.S., J. H. Teall, M.A., W. Topley, Prof. T. Wiltshire, F.L.S., Rev. H. H. Winwood, M.A., Henry Woodward, F.R.S., Assistant-Secretary, Librarian, and Curator: W. S. Lake, F.L.S.; Clerk: W. W. Leighton; Library and Museum Assistant: W. Rupert Jones.

Physical Society, February 28.—Prof. Guthrie, President, in the chair.—Messrs. G. R. Begley and O. Chadwick were elected Members of the Society.—Mr. J. C. McConnel presented two notes on the use of Nicol's prism. The first related to the error in measuring a rotation of the plane of polarisation due to the axis of rotation of the prism not being parallel to the emergent light. After pointing out the error was, to a first approximation, eliminated by taking the mean of the readings in the two opposite positions of the Nicol, the author proceed to push the calculation to a second approximation, so as to get a measure of the residual error. The result is given by the equation—

$$\frac{\theta+\theta_1}{2}-\psi=\text{const.}+\tfrac{1}{2}\alpha\rho^2\sin\psi\cos\psi,$$

where θ and $180+\theta_1$ are the two readings of the circle, ψ the angle between the plane of polarisation and a fixed plane in the ordinary Nicol, ρ the angle between the axis of rotation and the incident light. This equation is practically correct for a flat-ended as well as a rotation of 60° if ρ is less than 2°. The optical properties of the Nicol tend to neutralise the geometrical error due to the rotation taking place about one axis and being measured about another. The second note dealt with a new method of obtaining the zero reading of a Nicol circle. This is often defined as the reading when the plane of polarisation is parallel to the axis of rotation of the table of a spectrometer. A Nicol is fixed on the table, the light quenched by turning the Nicol circle, and the reading taken. The table is then turned through 180°, the light quenched, and the reading taken again. The mean of the two readings gives the zero required. It was described how the error due to the want of symmetry of the Nicol might be found and eliminated. Mr. H. G. Madan exhibited and described some new forms of polarising prisms. The first of these is by M. Bertrand, and has been described by him (*Comptes Rendus*, September 1884). The prism consists of a parallelopiped of dense flint glass of refractive index 1·658, the same as that of Iceland spar for ordinary ray. The glass prism is cut like the spar of a Nicol prism, a cleavage plate of spar being cemented between the halves by an organic cement of refractive power slightly greater than 1·658. A beam of light traversing the prism is incident on the spar at an angle of 76° 44′. The ordinary ray passes through without change, but the extraordinary ray is totally reflected at the first surface. The prism gives a field of 40°. M. Bertrand's prism has the great advantage of requiring only a very small quantity of Iceland spar, a substance that is becoming more scarce and expensive. The other prisms shown were a modification of one by M. Bertrand, described in the same paper; a modified image prism by Ahrens, described in the *Phil. Mag.* for January 1885; and a modification of the latter by Mr. Madan, described in NATURE for February 19. Mr. Lewis Wright pointed out a practical objection to M. Bertrand's prism that it would be doubtful whether a glass could be obtained of so high refractive index as to possess a refractive index of 1·658 and at the same time be colourless and unaffected by the atmosphere. He also pointed out that the principle of the prism was by no means new.—Prof. W. E. Ayrton read a paper by himself and Prof. J. Perry on "The most economical potential difference to employ with incandescent lamps." The authors commenced by pointing out the importance of experiments being made on the lives of incandescent lamps, in addition to experiments on efficiencies. Referring to the experiments on life given by M. Fousset in *The Electrician* for January 31, they showed that if p be the price of energy in pounds, n the number of hours per year that it burns,

...e lamp in hours, and $\theta(v)$ the number of candles ... to the lamp, $f(v)$ and $\theta(v)$ being expressed as a ... of the potential difference in volts $\frac{p \times H}{f(v) \times \theta(v)}$ stands ...st per year per candle, as far as the renewal of lamps is ... Also, if H stands for the cost of an electric horse-... year for the number of hours electric force is em-... and $p(v)$ the number of watts per candle, $\frac{H}{746} \times p(v)$ ... the cost per year per candle as far as the production ... is concerned. EDINBURGH

Physical Society, February 28.—The Rev. Prof. ... D.D., F.R.S.E., President, in the chair.—The follow-...unications were read, viz. :—Prof. W. Turner, F.R.S., ...and described a collection of fossil bones of mammals ...n excavating the new dock and a gas-holding tank at ...He was indebted for these to Dr. Leitch, Mr. Charles ...d Mr. J. T. Middleton. The specimens consisted of ...d a humerus of the Red Deer, vertebræ of two whales ...krulls and some of the bones of the limbs of the great ...of Britain, *Bos primigenius*. Those found in exca-...dock were within a short distance of each other, lying ...f wet gravel and shingle, mixed with oyster, mussel, ...e beds, the material overlying the bones being twenty-...thickness. One of the authors contained eight joints, ...doubtful if a finer specimen could be found on any ...ed deer. The lower jaw of one skull of the *Bos* ...us was obtained, and it is apparently the only speci-...had been seen in Britain, and, comparing it with the ...in Cadzow Forest, he found that the extreme length ...of the fossil ox was 18½ inches, as against 15⅞ inches ...milton cattle, being a difference of nearly 3 inches. ...ones also showed the massive character of the Great ...nabled the Society to realise its magnitude.—Dr. R. ...erray, M.A., M.R.C.P.E., described and exhibited ...modifications of recording apparatus.—Dr. Ramsay ...F.R.S., described and exhibited a new fossil fish, ...*s multistriatus*, found in the black-band ironstone at ...—Mr. George Brook, F.L.S., described a new ...e the aeration of marine aquaria.—Mr. John Hunter, ...ad a paper on a new modification of Lunge's nitro-...Prof. A. G. Nathorst and Prof. Gustav Lindström, of ...s, have been elected Corresponding Fellows of the ...

...tion of Civil Engineers, February 19.—Sir Freder...mwell, F.R.S., President, in the chair.—The second of ...f lectures on "The Theory and Practice of Hydro-..." was delivered by Dr. William Pole, F.R.S., L. and ...C.E., Honorary Secretary of the Institution, the ...ng "Water Supply."

CAMBRIDGE

...phical Society, February 16.—Prof. Foster, Presi...e chair.—The following communications were made ...iety :—Some remarks on the urea ferment, by Mr. A. ...on the occurrence of reproductive organs on the root ...*ria bulbosa*, by Mr. Walter Gardiner.—On the types of excretory system found in the Enteropneusta, by Mr. W. Bateson.

SYDNEY

Linnean Society of New South Wales, December 31, 1884.—C. S. Wilkinson, F.L.S., President, in the chair.—The following gentlemen were present as visitors :—Messrs. W. H. Caldwell, B.A., C. E. Smith, James Mosely, Alex. Hamilton.—The following papers were read :—Occasional notes on plants indigenous in the immediate neighbourhood of Sydney, No. 8, by Edwin Haviland.—The geology and physical geography of the State of Perak, by the Rev. J. E. Tenison-Woods, F.G.S., &c.—Note on an apparently new parasite affecting sheep, by R. von Lendenfeld. In several localities sheep were affected by a disease similar in appearance to epithelial cancer, which appeared on the feet behind the hoofs and on the lips. The histological investigation shows that the sete malpighii is inflamed and the papillæ attain a very large and abnormal size; the outer layer of the skin and the horny epithelium are very much thickened, and it is apparent that between the horny layer granular masses, apparently parasites, are disposed, in which nuclei can be detected. The author supposes these to be an Amœba, and to cause by irritation the hypertrophy of the epithelium. The sections were exhibited under the microscope; the specimens were hardened with chromic acid and stained with picric acid carmin.—On the temperature of the body of *Ornithorhynchus paradoxus*, by N. de Miklouho-Maclay. The result of some observations on the temperature of the *Ornithorhynchus* is here given, showing it not to exceed 40° C. or 76° Fahr. Previous observations made by the Baron had shown that the temperature of the body of the Echidna was at least 5° Fahr. higher than that of the other Monotremes.—Mr. W. H. Caldwell, B.A., exhibited several specimens which he had recently obtained in Queensland, showing the stages in the development of the Monotremes from the laying of the egg to the hatching.—Mr. J. Mitchell, of Bowning, exhibited a large number of Silurian fossils collected by him in the neighbourhood of Bowning. They consisted of a variety of mollusks, corals, and about sixteen species of trilobites. Among the trilobites are *Phacops caudatus*, *P. longicaudatus*, *P. encrinurus punctatus*, and *P. Jamesii* (?), *Calymene* (*Ceraria* ?), *Harpes ungula*, *Staurocephalus Murchisonii*, *Brontes*, and several of the genus *Acidaspis*, one of which attained a considerable size. The mollusks included representatives of *Pleurotomaria*, *Orthoceras*, *Avicula*, *Strophomena*, &c.

PARIS

Academy of Sciences, March 2.—M. Bouley, President, in the chair.—Note on "Les Origines de l'Alchimie," by the author, M. Berthelot. In this work the origin of alchemy, forerunner of the modern science of chemistry, is traced back by means of Greek manuscripts and Egyptian papyrases to the remotest historic times.—Researches on isomery in the aromatic series; heat of neutralisation of the polyatomic phenols, by MM. Berthelot and Werner.—Observations of the small planets and of Wolff's comet made with the great meridian at the Paris Observatory during the last quarter of the year 1884, communicated by M. Mouchez.—On the periodicity of the solar spots, and the anomaly of their last maximum, by M. Faye. The periodicity is regarded as established, and the irregularity in the last maximum is referred to a possible quasi independence of the northern and southern solar hemispheres, in virtue of which the epochs of their respective greatest activity may not coincide exactly.—First explorations of the mission sent by the Academy to study the recent earthquakes in the south of Spain, by M. Fouqué. The mission, consisting of MM. Fouqué, Lévy, Bertrand, Barrois, Offret, Kilian, and Bergeron, arrived at Malaga on February 7, and from that point visited Periana, Zafarraya, Venta de Zafarraya, Albama, Arenas del Rey, and Albuñuelas, which places suffered most during the disturbances.—On a characteristic reaction of the secondary alcohols, by M. G. Chancel.—Action of oxygenated water on the oxides of cerium and thorium, by M. Lecoq de Boisbaudran.—Correction of a previous communication (*Comptes Rendus*, February, 1879, p. 322) regarding the spectrum of Samarium, by M. Lecoq de Boisbaudran.—On the prevailing winds of North Persia, and on the south wind of the province of Ghilan, by M. J. D. Tholozan.—Report of the International Commission for the widening and deepening of the Suez Canal, presented by M. de Lesseps.—Election of M. Grand'Eury as Corresponding Member for the Section of Botany in place

of the late M. Duval-Jouve.—Reply to some of the criticisms, formulated in connection with the note of January 5, on the reproduction of phylloxera and the employment of the sulphate of carbon for its destruction, by M. P. Boiteau.—On the spectrum and formation of the tail of Encke's comet, by M. Ch. Trépied.—On a theorem of M. Darboux in mathematical analysis, by M. E. Picard.—The poles of the gyroscope and rotating solids in connection with Coriolis's theorem, by M. Henry.—On the maxim phase in the diurnal variations of terrestrial magnetism in 1882, according to the results obtained at the Montsouris Observatory, by M. L. Descroix.—Claim of priority in respect of the process of annulation of the extra current employed by M. d'Arsonval to avoid the dangers of mechanical generators of electricity, by M. A. Doussin.—On the means of counteracting or diminishing the dangers of the extra current in dynamo-electric machines in case of rupture in the exterior circuit, by M. J. Raynaud.—On the limit of density and atomic value of the gases, and especially of oxygen and hydrogen, by M. E. H. Amagat.—Composition of the gaseous products of the combustion of iron pyrites, and influence of Glover's tower on the production of sulphuric acid, by M. Scheurer-Kestner.—On the separation of alumina and the sesquioxide of iron, by M. P. Vignon.—On some basic and ammoniac nitrates, by M. G. André.—On the composition of the glyoxal-bisulphate of ammonia ($C_4H_3O_4$, $2(AzH_4O$, $S_2O_4)$, $2HO$), by M. de Forcrand.—Action of the sulphate of cinchonamine on the circulation and secretions, by MM. G. Sée and Bochefontaine.—On the substitution of quinine for creosote and phenic acid in the treatment of typhoid fever, by M. G. Pécholier.—Measure of the pressure necessary to determine the rupture of blood-vessels, by MM. Gréhant and Quinquaud.—On some peculiarities relative to the connections of the cervical ganglia of the sympathic nerve and the distribution of their afferent and efferent branches in *Anas boschas*, by M. F. Rochas.—On the nature of the placental neo-formation, and on the unity maintained in the development of the placenta, by M. Laulanie.—Note on the fœtus and placenta of a gibbon, by M. J. Deniker.—On some points in the physiology of the muscular system of the invertebrates, by M. H. de Varigny.—On *Bos triceros*, Rochbr., and on preventive inoculation against epizootic peripneumonia as practised by the Moors and Fulahs of Senegambia, by Dr. A. T. de Rochebrune. This variety of domestic ox, peculiar to Senegambia, is characterised by a third horn growing from the nasal process and identical in its constitution and development to the two frontal horns. The variety, which is of unknown origin, is thoroughly established, and from time immemorial has been inoculated by the natives with the virus of epizootic peripneumonia, a disease prevalent in the country.—On the mosses of the Carboniferous epoch, by MM. B. Renault and R. Zeiller.—Origin of the iron, magnesia, and zinc ores in and at the foot of the Jurassic Limestone hills on the periphery of the central plateau in France, by M. Dieulafait.—On a remarkable deposit of running water in the mines of Carmaux, Tarn, by M. Stan. Meunier.—Destructive effects of a waterspout which recently passed over the Argentan district, Orne, by M. E. Vimont.—A new method of observing stars during their transit across the meridian, by M. Ch. V. Zenger.

BERLIN

Physiological Society, February 13.—Prof. Fritsch produced a few specimens of *Lophius piscatorius*, and drew special attention to the two rays situated above the wide gape, and ending in flap-like appendages, which in some had the shape of a fly, in others that of a worm, and were used by the fish as bait to attract its prey. The jaws and fins were likewise covered with flap-like appendages, excrescences of the skin, which rendered the animal, especially in mud, completely irrecognisable. The peculiar development of the skin of this fish induced the speaker to search for corresponding peculiarities in its nervous system—peculiarities which he soon discovered in its medulla oblongata. He found there, on the posterior side of the medulla, and quite superficially situated, a group of huge ganglion-cells, recognisable by means of a lens, such as had hitherto been found only in Malapterurus. While, however, this latter fish possessed but two such gigantic cells, Lophius had a larger number of them, and these offered for study a series of general problems on the structure of ganglion cells. The protoplasm of these colossal nerve-cells was not fibrous, but granular, the nucleus large and bladder-like. The nutriment was provided by a close capillary net which closed tightly around the protoplasm and sent loops into its recesses. The cells were multipolar, yet one process, which in every case was peripherical, preponderated in size over all the other. From these cells there branched off gigantic nervous fibres of powerful fibrous axis cylinders and sheaths. These nerves were found partly also in the roots of the vagus minus, and probably spread to the peculiar cutaneous ages of Lophius. Altogether Prof. Fritsch believes justified in concluding from what he had observed in tions of the ganglion-cells of Lophius, that there are apolar nor unipolar ganglion-cells, but only bipolar polar, and that the processes of the ganglion-cells so that frequently an axis-cylinder would be produced ganglia.—Dr. Uhthoff spoke in detail of the experiments out by him in the Physical Institute regarding the of visual acuteness on light intensity. By way of the report on the subject given by Dr. Konig at ing of the Physical Society, be it here observed that among the eyes examined showed themselves even weak light intensities, and that the minimum of vis (1-1000th of the normal value) was, in particular observable under an illumination corresponding with of the petroleum lamp to a distance of 300 m. acuteness was further examined under a changing red and blue light. Red light, just as much as with increasing intensity a very rapid increase of The curve in the case of red light was, however, that in the case of white light. Under a blue sharpness very slowly declined with increasing Dr. Uhthoff next described an apparatus he had the purpose of measuring the angle of the visual line perpendicular to the cornea, without the use of meter. The principle of the apparatus was ing the angular displacement of a plane parallel the glass plate standing perpendicular first to the then to the (actual) visual line. Both the appar Uhthoff and the microscopical preparations of ganglion-cells and fibres of Lophius were shown in the demonstrating hall.

Diary of Societies

LONDON

THURSDAY, MARCH 12.

SOCIETY, at 4.30.—The Absorption Spectra of the Alkaloids, II.: W. N. Hartley, F.R.S.—Contributions towards the Solution of th cal Constitution of Isatin: The late Prof. H. Kolbe, For. Mem.R.S. truct of some Results with respect to Double Periodic Elliptic Func- d the Second and Third Kinds: J. Griffiths.

MATICAL SOCIETY, at 8.—On the Flexure of Beams: Prof. K. g.—On a Method in the Analysis of Plane Curves, Part 5: J. J. r, F.R.S.—Two Elementary Proofs of the Contact of the 1, of a Plane Triangle with the Inscribed and Escribed Circles, together Property of the Common Tangents: Rev. T. C. Simmons.—Another of the same: R. Tucker.—On the Geometrical Form of Perfectly ar Cell-Structure: Mrs. Bryant, D.Sc.

OF TELEGRAPH ENGINEERS, at 8.—On Constant Electromotive in an Electric Light Circuit: Sir David Salomons, Bart.—Electrical ions, Nomenclature, and Notation: Andrew Jamieson, F.R.S.E.

OF ARTS, at 8.—Recent Improvements in Photographic Develop- W. K. Burton.

INSTITUTION, at 7.—The Pianoforte Composers of Beethoven's Prof. Ernest Pauer.

NSTITUTION, at 3.—The New Chemistry: Prof. Dewar.

FRIDAY, MARCH 13.

OF ARTS, at 8.—Female Education in India: Manchorjee M. angrue.

NSTITUTION, at 9.—Accidental Explosions caused by Non-explosive : Sir F. A. Abel.

SATURDAY, MARCH 14.

Y SOCIETY, at 3.—Characteristic Curves and Surfaces of Incan- t Lamps: Prof. J. A. Fleming.—Discussion on Professors Ayrton erry's Paper on Incandescent Lamps.—Recent Researches on Radia- Capt. Abney, F.R.S.—Further Lecture Experiments on Spectrum ds: C. Cheshirshaw.—On Sir W. Thomson's Quadrant Electro- Dr. J. Hopkinson, F.R.S.

STS' ASSOCIATION, at 7.—Visit to British Museum.—Demonstration Carruthers on Cycads, Recent and Fossil.

BOTANIC SOCIETY, at 3.45.

NSTITUTION, at 3.—Richard Wagner: C. Armbruster.

SUNDAY, MARCH 15.

LECTURE SOCIETY, at 4.—Hinduism at Home: M. D. Conway.

MONDAY, MARCH 16.

OF ARTS, at 8.—Carving and Furniture: J. Hungerford Pollen.

, INSTITUTE, at 8.—Fossil Botany: W. P. Jones.

INSTITUTION, at 5.—Astronomical Lecture: J. Norman Lockyer.

TUESDAY, MARCH 17.

AL SOCIETY, at 8.30.—Report on the Collection of Birds made the Voyage of the Yacht *Marchesa*. Part I.: Dr. F. H. H. uard, M.A., M.D., F.L.S.—On the Butterflies of Timor-Laut: T. . Communicated by Dr. A. B. Meyer, C.M.Z.S.—Notes on the on Cliff-Swallow (Petrochelidon rufícolla): Prof. W. Nation.—Ob- ons on the Theory of Sexual Dimorphism: Jean Stolzmann.

ICAL SOCIETY, at 7.45.

OF ARTS, at 8.—The Congo and the Conference: Commander m.

NSTITUTION, at 3.—Digestion and Nutrition: Prof. Gamgee.

WEDNESDAY, MARCH 18.

METEOROLOGICAL SOCIETY, at 7.—Notes on Sunshine Records: H. Scott, M.A., F.R.S.—Results of Meteorological Observations at São Paulo, Brazil, 1879-1883: The late Henry B. Joyner, C.E.

OF ARTS, at 8.—Rivers' Pollution Bill: J. W. Willis-Bund.

OLLEGE SCIENCE SOCIETY, at 7.—Exhibition Meeting.

THURSDAY, MARCH 19.

OCIETY, at 4.30.

SOCIETY, at 8.—New Genera and Species of Hydroids from H. Collection: Prof. Allman (postponed from March 5).—Plants of y. Bastilisk, O'Neill, and Margaret Islands, South-East New : Wm. E. Armit.

NSTITUTION, at 7.—Pianoforte Composers after Beethoven's Time: rnest Pauer.

NSTITUTION, at 3.—The New Chemistry: Prof. Dewar.

FRIDAY, MARCH 20.

NSTITUTION, at 9.—Liquid Films: Prof. A. W. Rücker.

SATURDAY, MARCH 21.

NSTITUTION, at 3.—Richard Wagner: C. Armbruster.

MADAGASCAR AND FRANCE.

With some Account of the Island, its People, its Resources, and Development.

By GEORGE A. SHAW, F.Z.S., London Mission, Tamatave.

With many Illustrations and a Map.

This book is of unusual interest. Mr. Shaw traces carefully the origin and history of the French claims in Madagascar, and enables his readers to estimate accurately both the French and Malagasy positions in the conflict. The chapters on the "Origin of the Malagasy," "Malagasy Civilization," "The Present Civil and Religious State of the Malagasy," "The Fauna," and "The Flora of Madagascar" are full of attractive matter. He has throughout the vividness of an eye-witness, and the accuracy of one who writes from first-hand knowledge, while a personal interest attaches to many of it from the prominent part played by Mr. Shaw himself in the events described.

THE RELIGIOUS TRACT SOCIETY, 56, PATERNOSTER ROW, LONDON.

WOODHOUSE & RAWSON,

SUPPLIERS OF ALL ELECTRICAL APPLIANCES.

In Casks, 12/6 per 9 gals. In Bottle, 3/3 per doz. Impl. Pts.*

*Bottles charged 2/- per doz., and allowed at the same rate if returned; but they must be paid for with the beer.

Neither sugar, saccharum, nor any of the many new Brewing Materials are used in the manufacture of the "S. N." Stout; it is Brewed entirely from the finest Malt and Hops; it is, too, more hopped than Stout is generally; therefore, besides being very nutritious, it is an excellent Tonic and particularly suited for invalids, ladies nursing, or anyone requiring a good strengthening beverage. It is a "Sound Nutritious" Tonic, and very much recommended by Medical men.

WALTHAM BROTHERS,

TWENTY-SECOND ANNUAL PUBLICATION
(Revised after Official Returns) of

THE STATESMAN'S YEAR-BOOK.

ATISTICAL AND HISTORICAL ANNUAL OF THE STATES OF THE CIVILISED WORLD FOR THE YEAR 1885. Edited by J. SCOTT KELTIE. Crown 8vo. 10s. 6d.

'The Statesman's Year-Book,' now in its twenty-second year of publication, has become what such a work should be to its title—a volume unique for the amount and variety of the information it contains within a convenient compass. . . . This ain, as last, there has been a considerable addition to its pages, and Mr. J. S. Keltie must be complimented on the diligence esearches and the perfect co-ordination of his materials. . . . Nearly twenty pages are devoted to Egypt, so that we have a te statement of the actual condition of affairs in that disturbed country—political, military, financial, and commercial. In g that Mr. Keltie has done his work very assiduously and with a thoroughness which proves that he has drawn on sources of dion well nigh numberless we have only to say that he has made 'The Statesman's Year-Book for 1885' more trustworthy nable than ever."—*Times.*
